Spectrophotometric theory tells us that the measured absorbance of a compound is directly related to its concentration in solution. In other words as absorbance increases so does the concentration. If we test one mushroom for active tryptamines and find that it has an absorbance of 0.600 and then test another and find that it has an absorbance of 0.900, we can say that the latter one has a greater concentration of tryptamines than the first. Sure, we do not know the absolute concentration in mg/gram of the psilocybin/psilocin, but who cares? We can as easily relate to 0.600 A as we could relate to 2 mg/gram in our own subjective experience.

Because of the potential for ambiguity in the test results through the chromophore's multiple color reactions, it may be appropriate to review the literature to see what constituents of P. cubensis others have found in their research. Some of these other natural compounds will react with the test and add to the test value even though they are not active tryptamines. And others are active tryptamines which because of their somewhat different psychophysiological activity can modify one's trip significantly for better or worse. We need to know what these are, too.

As far as active tryptamines in the mushroom, the two with the greatest concentration in P. cubensis are, of course, psilocybin and psilocin.[13 p.109] The "tryptamine derivatives" are called such because of their similarity to serotonin. This class has an INDOLE group and a DIMETHYLAMINE group. The tryptamine derivatives include the brain transmitter substance, serotonin, the essential amino acid, tryptophan, the fast acting but short lasting psychedelic, DMT, and of course psilocin and psilocybin. "Active tryptamines" refers to the various psychedelic tryptamines, including psilocybin, psilocin and all their analogs. See Figure 1 for examples of the various tryptamines.

Repke points out that any psilocin detected in mushroom samples may in fact be an artifact caused by hydrolytic cleavage of the phosphate group off the psilocybin molecule in the handling and sample preparation.[14] In fact, other analogs can be easily formed by the various enzyme systems and the presence of oxygen. I tried to make this point in the first article when I emphasized the importance of low temperature, vacuum drying when preparing the mushrooms for storage or the care needed in preparing the mushrooms for ingestion, for it is these analogs and breakdown products which are most likely the cause of the headaches, mental cloudiness and achiness which are not normal side effects of synthetic psilocybin.

Most literature references which I read noted that little psilocin was present in mushrooms. They may not have been able to find any psilocin with the psilocybin, because it is an artifact or perhaps because of the ease with which psilocin is oxidized. In the work of Bigwood and Beug, however, they found that after the second flush the psilocin levels are significantly high. In fact, they range from about ten to thirty percent of the total active tryptamine concentration (concentration of psilocybin and psilocin in this paper).[4]

Apparently, baeocystin, which is another psychedelic analog to psilocybin and psilocin, plays a major role in the natural biosynthesis of the psilocin and psilocybin in the mushroom and it is present in small but significant levels in P. cubensis. Based on the various samples tested in the cited literature, the range extends from 0.001% to 0.02% baeocystin of the mushroom's dry weight. Repke and the others found that baeocystin was never found in mushrooms which did not already have psilocybin present also. To put this in perspective, psilocybin usually makes up about one percent of the dry mushroom weight. (Baeocystin forms a pink to purple to blue color reaction in the presence of Ehrlich's reagent, which is similar to the test reagent which I describe at the end of this article.)[14]

The researchers, Beung and Bigwood found through their TLC work that they could isolate 12 distinct spots (i.e. different compounds) on the silica gel plate. Besides psilocybin, psilocin and baeocystin, their tentative conclusion is that the other spots represent N-methyl and tryptamine analogs of psilocin and psilocybin.[3]

Another tryptamine found in mushrooms is tryptophan.[9] This will react with the test reagents with a similar color as psilocin and will consequently add a small amount of absorbance to any test result, giving a slightly false high reading.

The test which I used to quantify the amount of psilocybin and psilocin in the P. cubensis mushrooms reacts with other nitrogen containing compounds, although it is most sensitive to indole containing compounds when read at the prescribed wavelength.[10] The common amino acid, glycine, is one such nitrogen containing compound found in abundance in the mushroom.[18] Another nitrogen based compound which has been found in the mushroom is urea. The yellow color change of the test indicates the presence of one of these ubiquitous compounds. Luckily, yellow adds only a small amount of absorbance to the value of the active tryptamines when read at 570 nm, the test wavelength.[3]

Casale, in reviewing the literature, mentions that besides the compounds already mentioned, ergosterol, ergosteral peroxide and a,a-trehalose have also been found in the methanol extracts of the Psilocybe mushrooms.[5] I could find no other mention in the literature about other tryptamine analogs, toxins, enzymes or hormones which may be present in P. cubensis and thus affect one's subjective experience. Agurell, Blomkvist and Catalfomo[1] identified a lengthy list of possible tryptophan metabolites which might show up in the psilocybe mushrooms: 6-hydroxytryptophan; kynurenine; tryptophan; kynurenic acid; xanthurenic acid; psilocin; tryptamine; methyltryptamine; dimethyltryptamine; 3-hydroxyanthranilic acid; anthranilic acid; N-acetyltryptophan; and indoleacetic acid. Agurell and Nilsson[2] demonstrated in their paper a tentative biosynthetic route for psilocybin for which any of the intermediates could exist in the mushroom, too. The synthetic pathway proceeds from tryptophan to tryptamine to N-methyltryptamine to *N,N*-dimethyltryptamine to psilocin to psilocybin.

Any and probably all precursors to psilocybin can be found at one time or another in P. cubensis. Some may be bound to proteins or enzymes which may tie them up for any chemical reaction or assimilation in the body. The consequence of the presence of all these other non-active tryptamine or nitrogen containing compounds which react with the test reagent is to artificially raise the absorbance or apparent concentration. In testing, the change in the absorbance does not necessarily mean a change in the active tryptamine (i.e. psilocybin/psilocin) concentration at all. Some quick and easy tests for field or the non-technically inclined.

A simple test described in High Times to determine whether one has inadvertently purchased LSD laced mushrooms is to mash the mushroom in some methanol and let it sit overnight. Decant the methanol the next day and hold the extract up to a black light. If the liquid glows blue then you have LSD containing mushrooms, which, as far as I know, do not exist.[17 p. 252] Norland describes a few colorimetric tests which can be used to identify mushrooms which contain tryptamine derivatives.[13 p.116] You may find them more useful than the longer and more complicated test procedure at the end of this article. You do not require a colorimeter for test results and if you can live with an eyeball color comparison and your memory, you can at least estimate the concentration differences between mushroom flushes.

1. A simple test for indole-containing compounds and tryptamines is to crush a small piece of mushroom into 1/2 ounce of vodka or ethyl alcohol ("denatured alcohol" or the hardware store "shellac thinner" is fine) and mix. Add 3-4 drops of hydrochloric acid (or the hardware store variety called, "muriatic acid") then drop a pine tree shaving into the solution which will turn "cheny red" in the presence of indoles.
2. Another test for indoles uses a small crushed piece of mushroom in 1/2 oz. of either methanol or ethanol (or Vodka). If you are interested in testing for psilocybin use methanol; if psilocin use ethanol or vodka. The difference in solubility between the two active tryptamines account for the difference in the solvents used. Mix well then filter. Let evaporate overnight or use a steam bath or a hair dryer to dry. Spot the residue on filter paper and let dry. Spray or drop on the following developer. In order for the test to work effectively the developer must be made fresh. To make the developer, add one drop of 37% formaldehyde to 15 drops of concentrated sulfuric acid. Psilocin should turn green to black where as psilocybin should turn yellow to green-yellow; green is normal. Orange-brown indicates amphetamines or LSD.
3. Ehrlich's reagent is a name of a mixture which is used to detect indole compounds which have been separated on a TLC plate. After spraying the test solution on the plate, a colored spot will form where such an indole-like compound lies. The reagent is made from pimethylaminobenzaIdehyde (5%)

(abbreviated DMAB) in concentrated hydrochloric acid (HCl).[9] Another variation of the Ehrlich's reagent is 2% DMAB in HCl-ethanol (1:1). This reagent gave the following color changes: psilocybin turned reddish-purple then faded to violet whereas psilocin yielded a strong blue color which faded to violet.[18]

4. If you are interested in pursuing a TLC testing procedure, see Leung, Smith and Paul for the various solvent systems which can be used to separate out the constituents of the mushroom. Also, you will be able to use the information about the expected relative distances (Rf values) which psilocin and psilocybin will travel up the plate for each solvent system. This information plus a test reagent such as the Ehrlich's will help to establish if psilocybin or psilocin or both are present in the mushrooms you test.[9]

For my own TLC use, I found that the solvent system which Beung and Bigwood used in their research worked best. They found that they could obtain the greatest resolution of the most spots by using a solvent mixture of n-butanol-acetic acid-water (12:3:5) with silica gelplates.[3] In my use of this solvent system, T found that the solvent ratios mix well. Some of the other literature suggests solvent mixtures which are not homogeneous after shaking, but instead quickly separate out into two layers, making these other solvent mixtures difficult to use in TLC.

In my own separations, I used a UV light and the fluorescent version of the TLC plates for detection. I did not have access to a fine mist sprayer which is required if using the Ehrlich's reagent. I could only distinguish six spots in contrast to the twelve which Beung and Bigwood found when they used both detection schemes (i.e. Ehrlich's reagent and UV lamp). In another test procedure I made a test paper which can detect the presence of indole compounds by using p-DMAB (para-dimethoxybenzaIdehyde) as the detection reagent or chromophore. Although the paper is not sensitive to low levels of indoles, I found it useful for quick checks of mushroom extracts for the presence of psilocybin/psilocin.

p-DMAB Test Paper

1. Add 1.0 gram of p-DMAB to 28 mil of ethanol (denatured). Stir until dissolved.
2. Add water to the above mix until 60 mil total volume achieved.
3. Soak some filter paper in the solution and let dry completely. One can use a hair dryer to speed the drying but do not use too hot of an air flow. The heat will destroy the p-DMAB and consequently the test paper's usefulness. Store the paper in a tight jar in the refrigerator.
4. To use the paper add a drop of the extracted sample to the paper and let dry. Hold the test paper over the mouth of a bottle of concentrated hydrochloric acid. The fumes will develop the purplish/blue color quickly. If the fumes do not develop the color try adding a drop of hydrochloric acid on the paper next to the sample spot. As the hydrochloric acid diffuses into the filter-test paper and comes close to the sample spot, the color, purple or blue will form if the sample is positive for indole compounds.

The theory behind the reference colorimetric test

In the preceding sections I have outlined the general parameters of colorimetric testing and in the last section listed the procedures for several test which are easy to set up and read. The test which I have selected for measuring the active tryptamine content in the various experimental samples from the last four years, is based on a color reaction with paradimethylaminobenzaldehyde (DMAB). DMAB is the common reagent ingredient in several other tests mentioned above including the Ehrlich's test.

To review the general colorimetric test again, the indole part of the tryptamines reacts with DMAB in a solution conducive to driving the reaction to completion thus forming a colored complex which can be visualized or read with a colorimeter or spectrophotometer. The intensity of the color (i.e. absorbance) is proportional to the concentration of the tryptamine content of the solution. The use of this test is common in the literature in slightly different formats. The test which I developed for measuring the indole-like compounds, psilocybin and psilocin, was originally used in a slightly modified form to measure ergot alkaloids.[16] Lysergic acid and ergotamine tartrate are ergot derivatives - both precursors to LSD and other pharmaceuticals and can be tested using DMAB.

Besides the more sensitive but more complex HPLC (High Pressure Liquid Chromatography) testing procedures, various researchers have used other means of quantifying psilocybin and psilocin. Leung and Paul used a quantitative TLC (Thin Layer Chromatography) method in which the least amount of chemically pure psilocybin to cause a reaction with Ehrlich's reagent (a 5% solution of p-DMAB in hydrochloric acid) was compared to the least amount of a test sample from extracted mushroom tissue needed to induce a color change. One assumes that the psilocybin concentration is equal in both cases and then computes the percent concentration of the psilocybin in the mushroom by knowing the amount of mushroom which was extracted.[11]

Other Potential Chromophores

The test does not have to be restricted to DMAB as a chromophore. Although in the following testing procedure and in all the technical literature, para-dimethylaminobenzaldehyde has been used as a color developing agent, another chemical, para-dimethylaminocinnamaldehyde may be used. This particular developing agent will yield a much more intense color than the DMAB and will consequently be more sensitive.

This additional sensitivity may be necessary if you are using a more crude colorimeter with a broad bandpass filter (i.e. more than 30 NM). Instead of the accepted reading wavelength of 570 nm used for the DMAB test, you should use 625 nm for para-dimethylaminocinnamaldehyde.[15] But in most applications this increased sensitivity will cause too dark a reaction color to develop and thus be hard to read on the colorimeter scale.

Still another reagent used similarly to the DMAB reagent (Erlich's reagent) is the Pauley reagent. This reagent uses diazotised sulphanilic acid. It is more specific than DMAB in that it does not react with psilocybin or urea, but only with psilocin, giving a deep red-orange color.[18] (I do not have details on which wavelength to measure this color reaction.)

The Correct Wavelength to Measure the DMAB Chromophore

A few researchers used DMAB in their colorimetric test and generally the wavelength they used to read the indole containing compounds has been 570 nm. The spectrophotometric peak of both psilocybin and psilocin after reacting with DMAB is sufficiently broad so that one can use another wavelength close to 570 nm without affecting the sensitivity of the test. This could be important if you use a filter colorimeter and the available filters do not include the specific wavelength of 570 nm.

In figure 3 I have constructed a spectral absorbance graph for a positive DMAB test for some mushroom powder. I took transmittance readings every 10 nm from 400 nm to 610 nm and then converted the transmittance values to absorbance, which I later plotted. The best wavelength to read a colorimetric test is usually at one of the absorbance peaks. As you can see, the test could be read at more than one wavelength based on this criteria. Another possible absorbance maxima besides the approximate 580 nm peak is on the 550 nm peak. It is probable that these two peaks represent psilocin and psilocybin. The large peak around 410 nm may be a secondary peak for psilocybin, which is usually seen as purple - a combination of red and blue.

When analyzing the graph remember that this represents spectral absorbance not transmittance. Therefore for the color blue one would look for an absorbance peak in the red area of the spectrum (i.e. near 600 nm).

Light Speeds the Test Reaction

It was from the paper of Agurell, Blomkvist and Catalfomo which I discovered the principle outline of the test which T present here.[1] In that paper they suggested the use of a UV light which will speed the reaction with the DMAB chromophore. I have substituted that step by letting the reaction develop under fluorescent lights for a longer period of time. Even at that, the reaction continues to develop for 24 hours after initiation. The researchers mentioned also produced a calibration curve which could prove useful. But these researchers not only extracted the psilocybin but also purified it to some extent before testing their samples. You may be able to get a "ball park" absolute concentration in mg/gram of mushroom by extrapolating from this curve and by purifying your mushroom extract. Consult the reference for more details on purification if you are interested. (A future article will outline a purification procedure.)

The DMAB reaction requires at least thirty minutes to reach a plateau of color development under fluorescent light. Note figure 4 which shows this. Because the reaction actually continues for up to 24 hours, you will need to accurately time the development period and then standardize this time for all tests. I use 30 minutes because the greatest color changes have occurred by this time and I prefer not waiting too long for the results. Another good reason for using a shorter development time period is that psilocin and other related tryptamines which are present do gradually degrade, thus altering the value of concentration for the active tryptamines if allowed to sit in solution while the test is developing.

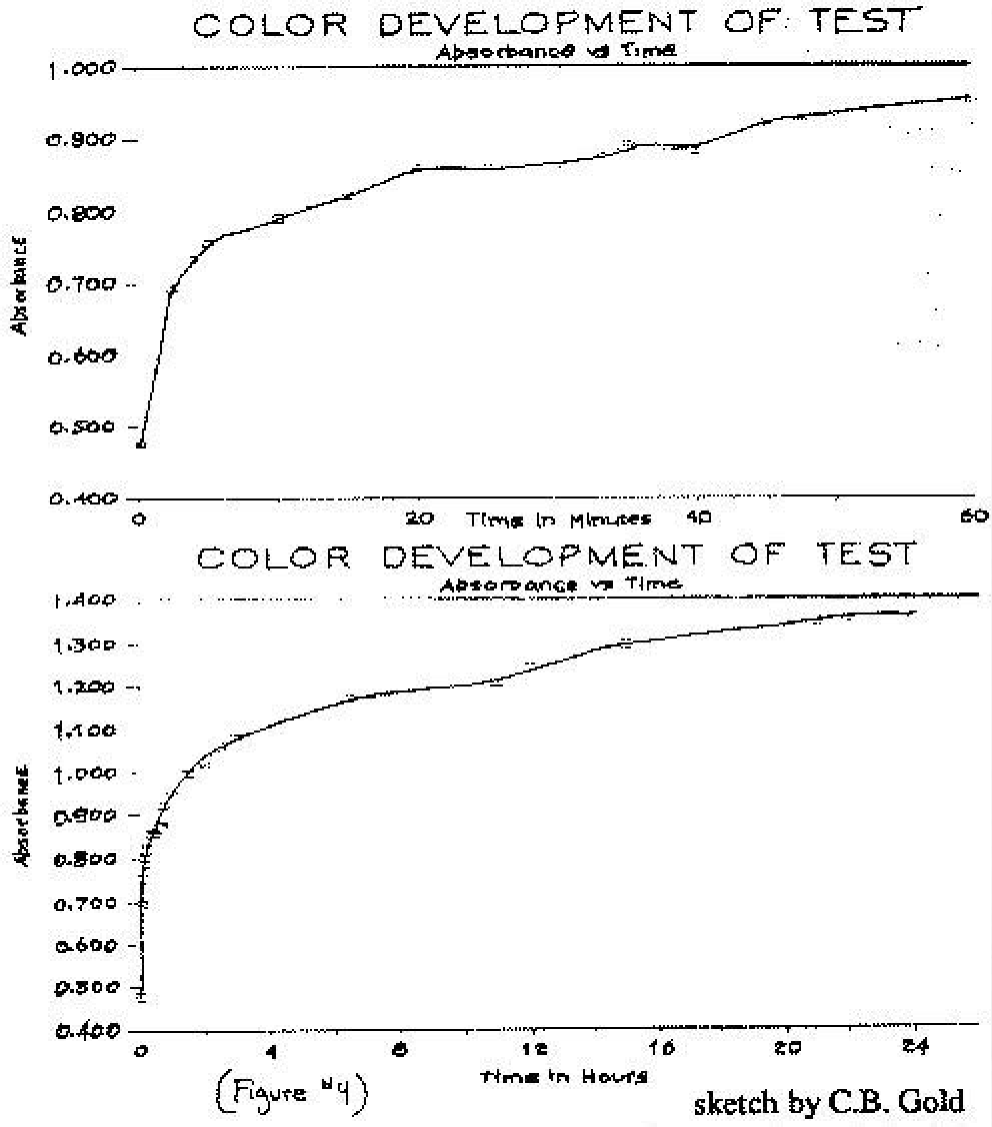

Figure 4 - Shows the time absorption scale surounding colorimetric testing.

Defining the Extraction Solvent

The researchers, Agurell, *et al.*, tested the extracted and somewhat purified psilocybin. They did not test for psilocin. To avoid a tedious and lengthy sample preparation, I wanted to extract, then read the mushroom sample without purification. Ideally, I wanted to use an aqueous solution to avoid organic solvents and to test for both psilocybin and psilocin during the same test. But psilocin has difficulty dissolving in water, and psilocybin is easily dissolved in water. Since psilocin is especially unstable in alkaline solution, I felt that an acidified aqueous solution would be the best to use as a solvent.[19] Many TLC tests confirmed that the acetic acid-water solution which I finally decided on did, in fact, extract both the psilocybin and psilocin.

I use an acetic acid-water extraction solution to help extract the psilocin and psilocybin more completely and also, to lower the pH so that the active tryptamines will be more stable. Without the acetic acid the solution will quickly react with atmospheric oxygen in the presence of endogenous enzymes to form a strong blue product and in the process destroy some of the psilocybin/psilocin. Also, the color blue itself will interfere with the test results, since the reaction yields a blue or purple color for tryptamines. Specifically, psilocin yields a brown-deep blue and psilocybin a yellow-green and purple color. In contrast, LSD will react with DMAB to form a blue-purple color.[17]

Apparently, others have also found that a dilute acetic acid solution is an excellent solvent for both psilocin and psilocybin. Not only does the solution completely extract both tryptamines but the solution extracts other interfering substances to a lesser degree. Casale also notes that if one heats the extraction solution of dilute acetic acid to 70 degrees centigrade for ten minutes, then the psilocybin is completely converted by dephosphorylation to psilocin.[5]

I have found on my own that heating the acetic acid solution eliminated whatever bluing reaction was occurring in the enzyme denaturing environment of the low pH extraction solution. That psilocybin is converted to psilocin is a plus, too. It means that the color reaction will form a more pure color and is therefore easier to interpret the test results.

Besides measuring the color of the developed reagent when it has stabilized somewhat, it is also important to measure a sample of the mushroom extraction as soon as possible. The dilute acetic acid slows the degradation of the psilocin-like tryptamines but does not totally inhibit this degradation. The longer you wait to perform the test on your sample, the lower the value will be. I found the reduction to be approximately 10% after 20 hours. Interestingly, the greater the concentration of active tryptamines as measured on a fresh sample, the greater the effect of time in reducing the apparent concentration.

Sample Weight

I arrived at the sample weight of 0.5 gram powdered mushroom by running a test on four sample masses: 0.2 grams, 0.5 grams, 1.0 gram and 1.5 gram. For the extraction volume of 20 milliliters, the 0.5 gram sample works best. The larger mushroom samples tend to float on top of the extraction solution in the large test tube and have to be constantly stirred so that the powder remains in the extraction solution. The smaller amounts of mushroom powder become increasingly harder to weigh accurately and precisely. Also, the smaller samples have less of a color in the developed reaction making it harder to read the spectrophotometer.

Other Influences on the Test

An interesting but unexplained influence on the color test came from a slight, but apparently significant, change in my standard procedure. If for some reason I used solvents in the preparation of the mushroom material and did not extract the mushrooms, but then totally evaporated the solvent leaving the original mushroom powder ostensibly unchanged, the test color shifted to a more pink color and consequently changed the absorbance from 570 nm. I noted this color shift primarily when I used methanol. Perhaps methanol reacts with something in the mushroom and this product in turn reacts with the DMAB. The point is that the test results cannot be compared to other test results for which you have modified the test procedures. Common sense may tell you that a particular modification may not matter, but in fact, the modification may change the results dramatically.

A more dramatic example of trying to compare apples and oranges as far as the colorimetric test for psilocybin/psilocin happens when I have tried to pre-purify a mushroom powder sample by extraction. My extractions were attempts to clean up the mushroom powder of non-active tryptamines. The colorimetric test becomes a more pure color but because other chemical entities have been removed which also react with DMAB, the overall absorbance drops, giving one the immediate impression that not as much psilocybin/psilocin exist in the mushroom powder sample when, in fact, just as much psilocybin/psilocin is present.

Interpretation of the DMAB Test

The DMAB test reacts with other than psilocin/psilocybin. The DMAB colorimetric test is not a perfect test. The numerical results can be somewhat misleading when used to indicate the concentration of psilocybin/psilocin, the two most common psilocybian analogs in P. cubensis. In the above section on "what is in the mushroom and what are we measuring?", I made the point that the test is not specific to just these two tryptamines. The test reacts with nitrogen-containing indoles, of which the tryptamines are a larger molecule which incorporates the indole group. The test is most sensitive to these indole-containing compounds but still can react with other indoles besides tryptamines.

DMAB reacts to form different colors with other indole containing compounds or other reactive nitrogen-containing molecules. For instance, psilocin typically is blue and psilocybin is purple or purple-green. And tryptophan which is chemically similar to both develops a deep blue color which is different enough from both to make it difficult to use as a standard as I had hoped.

The evidence one can obtain from the different color reactions for different indole compounds can help to evaluate the test results. Note the color mixture after the test has developed. Record the various colors. How pure a color are they? The more pure the color the greater the purity of the tryptamine present in the mushroom.

In my own TLC work I have consistently seen four separate bands which react with DMAB:

Zone	Rf	Color with DMAB
1	0.137	Dark Violet
2	0.275	Pure Violet
3	0.550	Grey Blue
4	0.965	Pink Orange

Each of the above "zones" represent a different chemical compound in the mushrooms which I tested.

By knowing that the DMAB test reacts with other indole compounds besides psilocin/psilocybin, one can conclude that the numerical results of the test represent the summed absorbances (i.e. concentrations) of the various tryptamines or other reactive compounds present in the mushroom, not just the absorbance of psilocybin or psilocin.

One needs to keep in mind that the DMAB test can lead to ambiguous results when trying to make conclusions about environmental or nutritional influences on the biosynthesis of psilocybin/psilocin. What may be occurring is a change in the mixture of the various tryptamines in the mushroom along with an increasing or decreasing or static test result. The ultimate confirmation would be the subjective test, because a change in the tryptamine concentration will change the nature of the psychedelic trip.

One can mistakenly interpret the test results in other ways. In addition to the extra absorbance because DMAB reacts with other compounds in the mushroom extraction besides the ones we are most interested, the general enzyme class of phenol oxidases which are widely distributed in different species of mushrooms can use DMAB as a substrate and can thus reduce the absorbance of the test artificially. By reducing the concentration of DMAB, these enzymes effect a falsely low value for the tryptamines. This is another reason I use a low pH extraction solution (i.e. acetic acid in water) and heat the extraction mixture. Both of these procedural details should reduce the likelihood of losing DMAB through enzymatic activity.[8,p. 108]

As noted in the article on harvesting and storage, some ions will interfere with the color development of the DMAB. In particular, my experience shows that the bisulfate ion inhibits the reaction. Sodium bisulfite can be an alternative to vitamin C as an antioxidant and enzyme inhibitor for mushroom storage.

Quantifying the contribution of non-psilocybin/psilocin factors which react to DMAB. When I began subjectively testing the effect of nutritional factors on the growth of my variety of P. cubensis, I noticed that the increase in absorbance of the DMAB test, which relates to an increase in concentration, did not seem to be proportional to the large increase in the subjective effects of the mushroom powder. A small apparent increase in the concentration (absorbance value) of the DMAB test doubled the subjective effects of the mushroom. My earliest concentration values for the mushrooms tested were 0.6 A (absorbance units). When I subjectively tested mushrooms which had increased to 0.8 A, I was surprised to have a trip which seemed twice as strong.

After careful thought, I concluded that the initial concentration value was composed of two or more colored constituents which added to the total value and that the active tryptamines which made the trip possible were a comparatively small percentage of this total color intensity.

To obtain evidence to confirm or deny this hypothesis, I used the process of paper chromatography to separate out three different mushroom powder samples measuring approximately 0.60 A, 0.80 A and 0.85 A by the DMAB test. After separating the mushroom extracts, I cut out the zone which corresponded to psilocybin, using its known Rf value for paper chromatography and a 2% solution of DMAB in ethanol and hydrochloric acid (1:1) to conclusively identify the width of the zone by its color reaction. After cutting out the psilocybin zone, I extracted it in 5% glacial acetic acid at room temperature overnight. I retested this extraction and compared the results with the extraction and test of the remainder of the cut up paper chromatogram which held the other factors in the mushroom extraction.

After correcting for variations in the sample volumes streaked on the paper and in spite of the poor separation achieved on the paper as compared to silica gel TLC, the results clearly showed that the other unknown but DMAB reacting factors in the mushroom increased their concentration with the increasing absorbance at a slower rate than psilocybin. In other words, the concentration of psilocybin increased with the increase in absorbance, which follows colorimetric theory, but as the absorbance increased, the psilocybin concentration contributed a greater percentage to the total color intensity of the various constituents which react with DMAB. This is in direct conflict with colorimetric theory which states that the concentration of a solution with an absorbance of 1.0 is twice that of a solution with an absorbance of 0.5. But colorimetric theory is for a solution of a single absorbing molecule and as stated previously, there could be as many as twelve different DMAB reactive compounds in the mushroom, each increasing its concentration at a different rate as stimulated by nutritional or environmental changes.

So at this point one can only say that as the absorbance of the test increases, the concentration of the active tryptamines increases - but we still do not know by how much. To try and answer this, I put together a graph at the end of my four years of research based on my subjective experiences of the strength of a trip as compared to the absorbance of the DMAB test. My log shows that I had at least several trips at several different concentration levels: at 0.5 to 0.6 absorbance; at 0.7 to 0.9 absorbance; at 0.9 to 1.1 absorbance and at greater than 1.1 absorbance. By using the intensity, duration and phenomenal experiences of the 0.5 absorbance experience as my reference, I compared each plateau with the previous one and then converted the increase into units of the base reference experience.

For example, I know from written records of my experiences that the second plateau (0.75 A) feels twice as strong as the first (0.5 A) and the third level is 1.5 times as strong as the second, and so on. The following graph (Figure 5) shows these results.

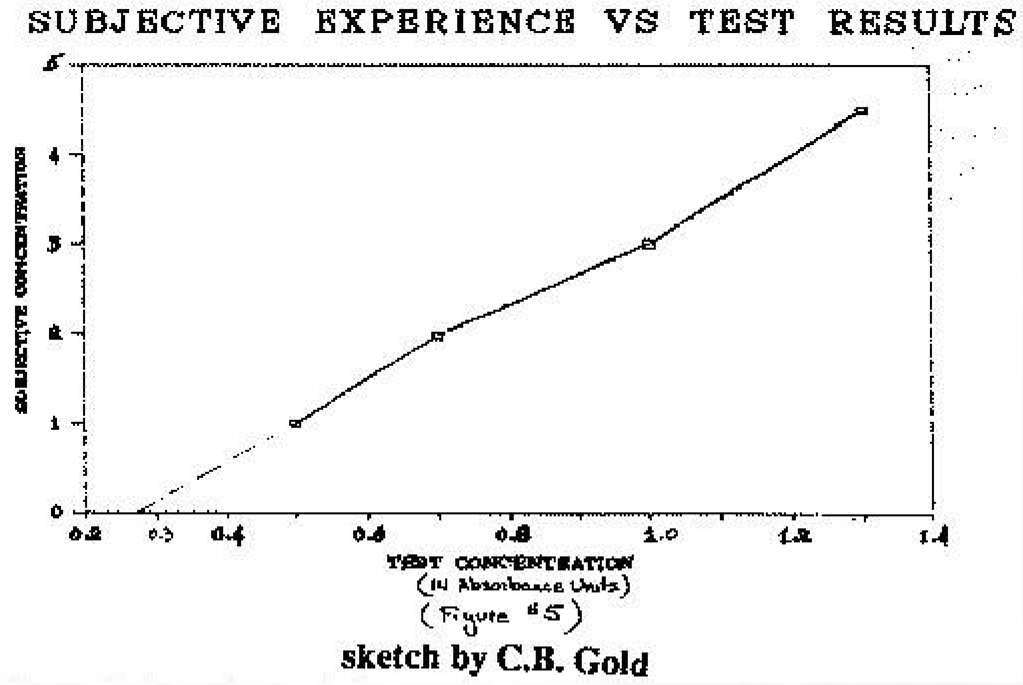

Figure 5 - Shows the psychedelic's trance strength compared to the colorimetric tests.

There are several points that we can glean from the graph:

1. The increase in the active tryptamines is in fact linear for this range and this variety of P. cubensis. Apparently for every increase in the mushroom test value of 0.2 to 0.3 A the experience intensity

increases by the equivalent of the 0.5 A mushroom experience.

2. The paper chromatography extraction experiment discussed earlier obtained a value of the other-than-psilocybin factors' absorbance as 0.35 A for the 0.6 A mushroom powder. The test was inconclusive on this matter because paper chromatography is such a rough separation procedure, but it suggests that the value for the absorbance for the other-than-psilocybin factors increases only slightly as the absorbance increases. Interestingly, if one extrapolates the subjective experience graph to the "0" experience point, the absorbance obtained corresponds to the point after which one will begin to experience the psilocybin. This extrapolated absorbance approximates 0.3 A which supports the paper chromatography results that showed that the first 0.3 A of a mushroom test value is color from non-active tryptamines and other DMAB reactive compounds. The value also means that all the samples had at least 0.3 A of non-active, but DMAB reactive, junk in the mushroom. Of course some of the active tryptamines, which can intensify the trip, may not necessarily be a pleasant addition to the trip either.
3. Although my work on increasing the concentration of active tryptamines through environmental and nutritional manipulation was successful, my secondary goal of reducing the concentration of the junk in the mushroom was not particularly successful Apparently, the level of non-active, but DMAB reactive substances, stayed about the same. It is impossible for me to know without more extensive testing using HPLC whether as the concentration increased, the mixture and relative concentration of the various active tryptamines, such as psilocybin, psilocin, baeocystin and their analogs, changed in the mushroom powder.

In conclusion, then, when reading the upcoming article(s) on growth factors for P. cubensis, keep in mind that as the test values go up the subjective experience increases in intensity, too. But, an increase in the objective test value cannot be used to predict an equivalent percentage increase in the subjective experience. In fact my experience has shown that for a modest increase in the test absorbance, I increased the subjective amount of active tryptamines two or even three times.

Colorimeters

I acquired a used Bausch & Lomb Spectronic 20. I understand that not everyone is in the position to so easily buy such equipment. Try the yellow pages for used laboratory equipment dealers. If not specifically listed, try laboratory suppliers. Usually, they have a service department and may have used spectrophotometers or colorimeters. Some brand names to look for are older models of the Bausch & Lomb Spectronic 20, the Coleman Jr. and the Turner. These companies sold many of these lower cost spectrophotometers for many years and you might be able to buy one comparatively inexpensively, say 100 to 200 dollars.

Another option is to buy a new colorimeter but without all the expensive features that the above units have. For the application of reading at a fixed wavelength and a broad color peak, such as in this test, a low cost colorimeter is all that is necessary. All it needs is the proper filter (i.e. as close to 570 nm as possible), a cuvette or test tube holder and a scale in per cent transmittance.

There are three companies that I know of which can offer a low cost colorimeter:

- Chemtrix (P.O. box 1359, Hillsboro OR 97123; 800-821-1358) has a colorimeter (20A) for $269;
- Hach (P.O.Box 389 Loveland, Colorado 80539; 800-525-5940) has a single parameter DR100 colorimeter for about $200 (contact Hach about supplying a transmittance scale and the proper filter)
- Hellige (877 Stewart Ave., Garden City, N.Y. 11530; 516-222-0302) has a meter readout photometer for about $125.

Balance

The Ohaus triple-beam balance is a recognizable standard school lab scale. Presently these cost about $80 to $90 from almost any lab dealer or even hobby shops or some specialty hardware stores. But for this test and most work with mushrooms, you will not need the capacity, or ability to weigh large as well as small masses, offered by this triple-beam. I do not have company names but I have seen in High Times advertisements for small, Inexpensive scales which can weigh accurately up to 30 grams.

Large borosilicate test tubes

Of the twelve test tubes set aside six. These will be used "as-is" with out matchine. The other six need to be volumetrically marked for the standard extraction volume of 20 milliliters. To do this, simply fill up the 20 mil volumetric pipette with water then add it to the test tube to be marked while standing in the test tube holder. Then mark the bottom of the meniscus with an indelible marking felt pen. Do the same with the other five test tubes.

Matched cuvettes

Cuvettes should be one centimeter ID, but because of variations in the extrusion Process for the tubes the ID differs slightly. This irregularity in the internal diameter and the occasional streaks or variations in the thickness in the glass walls of the tubes will result in cuvette-to-cuvette differences in the amount of light from the colorimeter filter passing through the cuvette and solution. This variation can be as much as five percent transmittance. To increase test-to-test precision, some of the manufacturers of the colorimeters mentioned above offer matched cuvettes as an option. Matched cuvettes have been selected so that the amount of light which is absorbed by the walls of the cuvette is essentially the same from cuvette to cuvette. For the price it is usually easier to buy them. If you have to prepare matched cuvettes follow this procedure:

1. 13 mm OD culture tubes will have a nominal ID of 10 mm. Buy at least a couple of dozen.
2. Chose several and fill them with water. Insert them into your colorimeter and set the wavelength to 570 nm or as near as your filter will allow.
3. Set the meter to an arbitrary mid-meter position. Then slowly rotate the cuvette. Notice the variation as you rotate the cuvette the full 360 degrees. Choose the culture tube with the least variation.
4. Continue with another set of a few cuvettes and keep selecting the least variable cuvette until you have six to ten cuvettes.
5. Now match the cuvettes by making an arbitrary mark with nail polish or airplane enamel on the open lip of a cuvette such that this mark can be used to align the cuvette in its holder. Note the meter readout.
6. Take another pre-selected cuvette and rotate it until it matches the transmittance of the first marked cuvette. Mark it with nail polish or paint, too.
7. Continue until all the cuvettes are matched and marked. When using the cuvettes to measure the transmittance of the DMAB test reaction, be sure to always align the mark with the pre-determined alignment position in the cuvette holder. Usually the holder itself has a mark or ridge to reproduce the correct cuvette position.
8. It is possible that the initial cuvette which you arbitrarily marked may not match any or only a few other cuvettes. Just start over but use another cuvette as your initial reference cuvette.

Test Tube Holder

The particular holder I use is an open style which is one tube deep and seven across. I use this holder for heating the extraction solution in a one quart pan. To make it fit in the pan, I cut the holder in two sections of three test tube capacity each. When using this holder with the test tubes make sure you balance the weight of the tubes in the three slots. The holder tends to float. For instance if you put a single test tube in the holder's end, the holder will float up dumping the tube into the heated water and thus losing your mushroom sample. To avoid losing your sample, when extracting a single sample put the tube in the center of the holder, or if using two test tubes, put them on either end of the holder.

Chemicals

I have used technical grade chemicals throughout all my testing. Technical grade is somewhat less pure than reagent grade and usually less expensive. The sulfuric acid could be reagent grade which would be somewhat clearer than the slightly yellow-brown technicalgrade. Sulfuric acid is used in the color development solution and is read on the colorimeter, so clarity and lack of particles floating around would help readability and reproducability. I have had no problems with the less expensive technical grade by always using a sample blank to compare all mushroom test samples against it. A sample blank is used in colorimetry to set the "zero" point. It is usually the test reagent with a distilled water sample rather than the material or extraction to be tested. If the test reagent is colored in the spectral region of the test before any reaction, then by using a sample blank one can offset the colorimeter by this degree of color so that the test result is not artificially high.

Plastic sheet

All that is necessary is a piece of plastic to cover your thumb so that when you shake the culture tube with the test reaction mixture the sulfuric acid will not burn your skin. A piece a couple inches square should suffice. Most plastics are unaffected by sulfuric acid.

Testing Solutions Preparation

Color development reagent

This mixture is the actual solution which when in the presence of an indole or indole-like compound will develop a color from a near colorless solution.

1. Weigh out 0.2 gr of p-dimethylaminobenzaIdehyde (DMAB) and put it into the 250 mil beaker.
2. Make a 20% aqueous ferric chloride solution by weighing out 20 gr of the ferric chloride into 100 mil of distilled or Deionized (DI) water in the 250 mil graduated cylinder. Wear gloves. Ferric chloride can be corrosive. Make sure it all goes into solution. If any particles remain insoluble, filter the solution. Store the finished solution in a 125 mil bottle and label. Rinse out the graduated cylinder.
3. Using the 1 ml pipette and the pipette-aid (never suck up corrosive or toxic chemicals in a pipette!) draw up 0.3 mil of the stock ferric chloride solution (#2,above). Add this to the 250 mil beaker with the DMAB already in it.
4. Add 35 mil of distilled or Deionized water to the 250 mil beaker and stir the water to dissolve the DMAB as much as possible.
5. Add 65 mil of Sulfuric Acid from the graduated cylinder to the beaker with the DMAB. Be careful with sulfuric acid. Wear gloves, an apron and preferably a face shield. When adding the acid, set the beaker on the table. Do not hold the beaker. An exothermic reaction will take place when you add the acid to the water present in the beaker and it will be too hot to hold. Gently stir the mixture. The heat of the acid-water mixture will drive the remaining DMAB into solution.
6. Let the mixture cool down and pour this stock solution into a 125 mil bottle and label it. Do not put hot liquids into the bottles; they may break.

Store the DMAB solution in a dark, cool location, preferably in the freezer section of your refrigerator. If you cannot store it somewhere cold, the solution will gradually darken and thus be unusable for colorimetry. I have successfully stored my stock solution in the freezer for over a year and it has not darkened noticeably. At room temperature you will probably need to discard the solution after a few months.

Acetic Acid Extraction Solution

This stock solution is used to extract the mushroom of its active tryptamines. Then a sample of this extract is tested using the above DMAB color development solution.

1. Measure out 50 mil of glacial acetic acid in the 250 mil graduated cylinder. Fill the cylinder to the 250 mil mark with DI or distilled water and pour it into the 1000 mil bottle. Rinse the cylinder with 3 X 250 mil amounts of DI water into to the 1000 mil bottle to make a total of 1000 mil stock solution of 5% Acetic Acid.
2. Distilled vinegar (i.e. "white vinegar") can be substituted for 5% acetic acid. Distilled vinegar is approximately 5% acetic acid.

(Figure #6)

Figure 6 - Shows the basic procedure for colorimetric (p-DMAB) testing.

1. Set up the table or bench on which you will do your test with all the equipment in the above illustration spread out. Turn on the colorimeter or spectrophotometer to begin warming it up and adjust or set the proper wavelength (570 nm or close to this). Most have light sources which need to be on for 20 to 30 minutes to stabilize the spectral output. The older models also have slow-to-warm-up electronics.

2. Turn on the heating plate and begin to heat the water filled quart pan. Do not let the water boil. The boiling action will tip over the test tubes with the samples spilling out into the boiling water.

3. If you have not done so, use a coffee mill to grind up the dried mushrooms which you wish to test. Weigh out 0.5 grams of the ground mushroom. It's best when using a scale to use a piece of paper on which you weigh the mushroom. Find out how much this paper weighs before adding any mushroom powder then add this weight to the required half gram sample. This total weight in grams is what you should set the scale for if you have a triple beam-type scale. With the weighed mushroom powder on the weighing paper, cup the paper to form a trough and pour the sample into an empty, large (20 mm X 150 mm) unmarked test tube.

4. Add 20 mil of 5% Glacial Acetic Acid to the sample. Stir the sample with a glass stir rod making sure all the mushroom powder is wetted with the acetic acid solution. Put the test tube in the plastic holder and immerse the holder in the preheated near-boiling water. Note the time or start a timer. Heat this suspension for 30 minutes. This time is not critical. If you should heat it for longer than thirty minutes it will not make much difference. Too long will oxidize the psilocin in the solution and cause a false low reading of the sample. Also, the acetic acid solution does evaporate.

   Every ten minutes or so stir the suspension with the stirring rod. The mushroom powder tends to float on the acetic acid solution which cannot optimally extract the mushroom powder when it is not suspended. Also, the top of the powder can be exposed to air and will oxidize to a dark blue. Again, this can lead to a false low reading.

   The immersion of the glacial acetic acid solution in near boiling water with the mushroom powder during the extraction phase of the test is important to deactivate any enzymes which can cause bluing, and thus tryptamine loss, in the mushrooms.

Without heat and with time the mushroom extract solution will slowly turn blue-green until it becomes dark blue after several days.

As noted in the above section on theory, use a thermometer to make sure that the extraction solution reaches 70 degrees Centigrade for at least ten minutes. This temperature converts all the psilocybin to psilocin which makes for more pure test color.

5. While the mushroom powder is extracting, set up the next step: the filtering and sample development. For each sample, use one small filtering funnel. In the funnel put a polyester ball. Using the wash bottle, wet the cosmetic ball then press any excess water out of the cosmetic ball with your finger. Discard this water if it went into the collection test tube.

6. After 30 minutes or so, remove the test tube holder from the water bath. Turn off the heat plate (or stove). Just before the initial filtering, stir the suspension one more time. Pour the test tube contents over the top of the polyester cosmetic ball in the small filtering funnel which drains into a large (20 X 150 mm) test tube on which you marked the 20 mil level. Do not worry if you cannot get every last drop of the suspension out of the test tube.

   Let the filtrate pass through the small filter completely by gravity. Sometimes pressing the cosmetic ball will succeed in driving more water extract off the polyester fibers. This step is important because if you don't get all of the original, undiluted extract in the final test sample, your concentration value will be falsely low. I have occasionally forgotten to do this squeezing step and have had readings which were off by 25%.

   Although you could get more consistent results by just using filter paper instead of the cosmetic ball, by filtering the thinly mucilaginous mushroom suspension with the cosmetic ball you can save literally hours of waiting for all the suspension to get through the paper filter.

7. Now use the wash bottle filled with distilled (or deionized) water and rinse the sides of the test tube used to extract the mushroom sample with a few milliliters of water. Note that the cosmetic ball filtered extract does not reach the 20 mil mark on the test tube. This loss of fluid came primarily from evaporation when you were heating the mushroom suspension.

   For reasons of standardization all our test solutions need to have a total volume of 20 mi. Shake the unmarked test tube which you just added some rinse water to and pour an estimated amount of the rinse water which will fill up the test tube to the 20 mil mark over the cosmetic ball filter. This rinse will remove most of the residual extract left on the polyester ball and will dilute the initial filtrate up to the 20 mil mark. Watch the filtering carefully and remove the filter to the sink once the level has reached the 20 mil mark.

   The largest errors can occur in the filtering and dilution steps. If in the process of washing the filtrate and bringing up the filtered volume to the 20 milliliter mark, you add too much water to the top of the funnel filter you will dilute some of the extracted sample which will not then pass through the filter.

   Since you have reached the 20 ml mark you are forced to discard the water which may contain some of your sample. The results may then be artificially low. Solution: add smaller amounts of rinse water with the squeegee bottle, so that you will not leave any of the liquid mushroom extraction on the filter that will then not be part of the test.

   If in the process of rinsing the sample on the cosmetic ball and adjusting the 20 mil volume, you should over-fill the test tube beyond the 20 mil mark, just correct the final absorbance by multiplying the absorbance by a fraction consisting of the volume which was filtered (over 20 milliliters) as the numerator and 20 as the denominator.

8. This rough filtered extract is your test sample but needs to be filtered again so that it is clear and will not add absorbance to the colorimeter reading because of its cloudiness. Pour this extract through another small plastic funnel with a folded piece of filter paper in it. Fold the filter paper on itself three times (i.e. into eighths).

   Most extracts will have some colloidal suspension in them, making them look slightly cloudy. Even filtering these with a fine filter will not remove all the turbidity. For most filtering you will need to remove only coarse particles and the Whatman #4 filter paper will suffice. For heavier suspensions use the finer, but slower, Whatman #2 filter paper. The idea here is to obtain a reasonably clear sample which has the least amount of turbidity. Turbidity, if excessive, will give false high colorimetric readings.

   For the receiving container for this filtrate, use another large test tube as the receiver. After a few milliliters of fluid has passed through, you can stop the process if you wish. I usually like at least enough prepared sample for a couple of tests (each tests requires 0.5 or 1.0 ml of sample), just in case I wish to repeat a reading.

9. The preceding two-step filtering process should take 10 to 15 minutes. While the filtering is proceeding, using the pipette-aid and the 10 mil pipette, draw up 2 mil of the DMAB reagent and dispense it into a matched cuvettes/small test tube. Continue dispensing the DMAB reagent into a matched cuvette for each sample or test you may wish to run. Now you are ready to develop the color and read the final absorbance. If you store the DMAB test solution in the freezer, allow it to return to room temperature before using it in a test.

10. Using the pipette-aid and the 1 mil graduated pipette, draw up a 1 ml sample of the mushroom extract to be tested. If you anticipate an absorbance reading above 0.700 A or so, then draw up only 1/2 mil of sample, but before doing so add a 1/2 mil of Deionized or distilled water to the small reaction test tube/matched cuvette.

    The reason for this dilution is that for colorimeters with a transmittance scale, the most readable portion of the scale lies above 20% transmittance. Lower transmittance than this corresponds to higher absorbance and greater possibility of reading errors and poor precision. I checked to make sure that both ways of testing equaled the same value after making the necessary multiplication of the diluted sample by two.

    The total combined test volume must be 3 mil for both the sample and the DMAB reagent. The aqueous sample will not immediately mix with the much denser DMAB reagent but will rest on top until mixed.

11. Make sure your timer is ready. Hold your thumb over the reaction tube with the plastic sheet between the thumb and the test tube and turn the tube upside-down then back again. Do not shake because the shaking will add bubbles which can remain on the walls of the test tube and interfere with the colorimetric reading later. Either start the timer or note the time immediately. After exactly 30 minutes, read the transmittance on the colorimeter (or absorbance if your instrument has a direct liner conversion to absorbance from transmittance).

    Sometimes the reaction mixture in spite of filtering the sample will become turbid. If so, dilute with 3 ml of DI water, read and divide the absorbance result by two. This dilution will usually water down the turbidity enough to be able to read the test.

    It is important to test the mushroom extraction solution soon, otherwise the bluing and other oxidation reactions will breakdown the active tryptamines and cause you to have a false low value for the test's absorbance. By testing the mush- room extract solution at regular intervals, I found that no significant reduction of the active tryptamine concentration occurred until after six to eight hours.

    I have always conducted this test under two 40 watt fluorescent lamps. In light of the research paper which used UV to accelerate the DMAB color reaction[6], fluorescent lamps may have more of their spectral output in the near UV than incandescent lights or sunlight coming through a glass window. The absence of such lighting in your test area may slow the reaction down and thus cause you to have lower readings after the 30 minutes than mine. I have not confirmed this, but be aware of this possibility.

12. At the end of 30 minutes, read the colorimeter scale and note the value for later reference. When reading the meter (unless the meter is digital) look directly down on the needle to the scale. If you should read the needle at an angle, your reading will not be as accurate, nor reproducible. As the value of the transmittance becomes smaller, errors in reading make a greater difference in the final absorbance (or concentration) value. Some meters have a mirror below the scale. By looking down on the needle such that you cannot see the needle's reflection, then you know that you are looking directly down on the needle and meter. Try to interpolate or "guesstimate" the value if the needle should fall between two divisions and show this as part of your recorded value (e.g. 14.6%) If you have a colorimeter or spectrophotometer with a direct absorbance output, your test value will be directly proportional to concentration of the tryptamines present in the mushroom sample. If, on the other hand, your colorimeter has a transmittance scale (i.e. 0-100%) and only a log absorbance scale (i.e. the distance between integers gets smaller as the numbers get larger), you will need to convert your transmittance to absorbance. The formula is: Absorbance Log (1/.01 X Transmittance in %).

    The easiest way to calculate this is to buy an inexpensive calculator with a "log" and "1/x" or reciprocal functions. Then calculate by entering the transmittance as a number between one and one hundred, divide by 100, push the "1/X" key then push the "Log" key. The result will be the absorbance which is proportional to concentration.

Conclusion

It is my hope that the above helps to explain the test values which will be used in the upcoming articles. The next article on the environmental and nutritional influences on the growth and biosynthesis of psilocybin in P. cubensis will make use of this test extensively. The last section of this article, of course, is for those people inclined to do their own testing. I encourage anyone with any amount of chemistry background to try this test. The test values will help immensely in planning your own entheogenic experiences with the "magic mushroom."

Fly Agaric Mushroom *(briefly)*

Wednesday, 16 May 2012

original source: http://lymeuk.blogspot.com/2012/05/fly-agaric-mushroom.html

Within half an hour I was transformed from a demented cripple into a normal person...

Amanita muscaria

Background

Fly agaric is used by sub-arctic NW Pacific peoples to treat psycho-physical fatigue, dementia, chronic fatigue, sclerosis, low immunity, skin problems, rheumatism, neuralgia and tumours. Lyme disease is endemic in the areas where these people live.

Theory

From what I understand, and what my LLMD (Lyme Literate Medical Doctor) has told me, the muscarine in the fly agaric mushroom is a neuro-transmitter. It forces open the muscarinic receptors, a form of acetylcholine receptor that plays a crucial part in the relay of electrical signals around the body. It is possible that these muscarinic receptors have become clogged with the neurotoxins created by the Borrelia bacterial infection. It's possible that neurotoxins from other infections could also have this effect.

Lymphocytes have muscarinic receptors too, so with muscarine they're able to do their jobs better, boosting immune defence. Fly agaric mushrooms also contain other chemicals with antimicrobial properties. The mycelium that creates them is like a plug-in immune system for the tree they attach to. It is believed that people can benefit from this antimicrobial activity also.

The raw, fresh mushroom contains ibotenic acid, which can give you an upset stomach. It's necessary to dry or cook the mushroom, which turns the ibotenic acid into muscimol, which won't upset your stomach. The small amount of muscimol may lift your mood a little.

Identification

The fly agaric mushroom is the classic toadstool of fairytale, a red mushroom with white spots. It is found throughout Britain, the season stretching roughly from late August to early December, under birch, oak or pine trees. It's unlikely to be confused with any other mushroom. It's best to take good fresh specimens, with either an open or closed cap.

Collection

Pick the whole mushroom. Take a non-metallic tool such as a clean wooden spoon to dig an inch or so around the base of the stalk. Sometimes it's possible to simply hold the stalk as low as possible and gently jiggle and pull it loose.

The mushrooms are the fruiting bodies of an underground mycelium in symbiotic relationship with the host tree. You can sustainably collect all fly agaric mushrooms you find, though it's best to take only the good fresh ones for medicinal use.

Wrap the mushroom in a large leaf, eg a dock leaf. Newspaper will stick to the caps.

Preparation

Wash the mushroom thoroughly. It doesn't matter if the white spots wash off. Try not to get the gills wet though, as they take a long time to dry again.

Cut out any bad bits or bits with wormholes in. You can use these to spread the fly agaric spore to another birch, oak or pine.

There are then several ways to prepare and preserve the mushroom:

Drying Whole

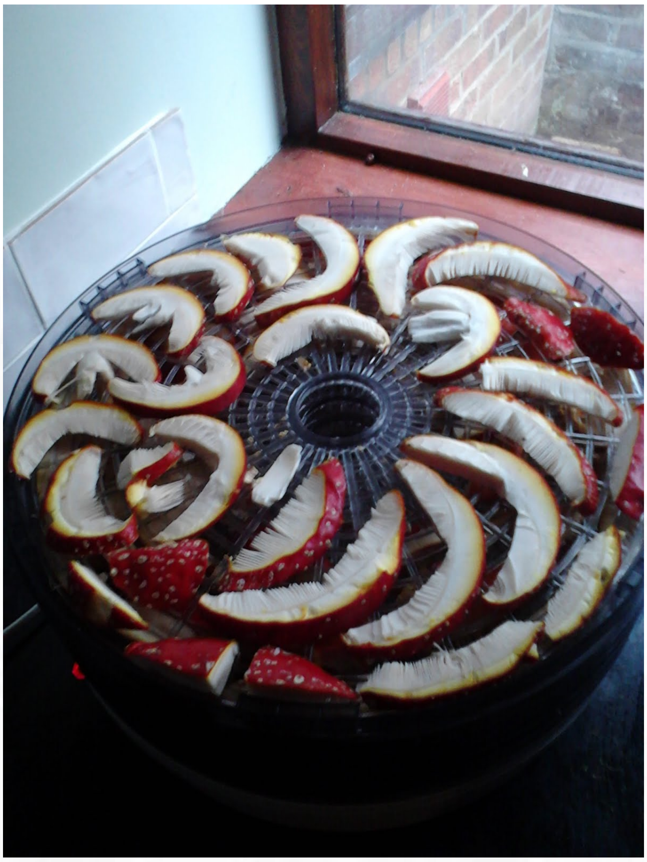
Use a skewer or thin stick to pierce the mushroom along its central axis. Leave on the skewer or thread onto a string. The image shows a Siberian rig. Dry in the hot air above a fire. This will take several hours, perhaps even more than a day. Once dry, keep in an airtight container, preferably with some desiccant in.

Break off pieces as required to eat or crumble into tea.

Drying Small Pieces

Cut the mushroom into thin pieces, around 2mm thick. They will dry more easily and quickly this way. Dry in a food dehydrator, or in the warm air above a fire, or in a warm airing cupboard. The image shows an improvised dryer near a solid fuel stove.

Overall I would probably recommend a food dehydrator. They're so easy to use. You can dry all sorts of other things in them as well, other plants to help treat your chronic illness, or fruit and vegetables for healthy treats. An open fire in the centre of a yurt would be best, but without that option, or an always-hot Aga, nothing is as easy as a food dehydrator. Mine only has one setting, but still does everything I ask of it.



Dry until the mushroom pieces are like crispbread, with all moisture gone. This will take several hours. Store in an airtight container, preferably with some desiccant in.

Eat a piece or crumble into tea as required.

Make Into Tincture

Cut the mushroom into small pieces (around 2cm square) and place in a jar. Cover with vodka or another 37-40% spirit. Shake a few times a day for 10-14 days. Filter through a muslin sheet. Store the mushroom vodka in a cool dark place.

Apply externally to relieve sciatica and other pain, including joint pain and swolle lymph nodes. The tincture can also be applied to external infections, for example nail fungus, and skin conditions found in Lyme disease.

Drops can be applied under the tongue to improve cognition in the short term.

The leftover mushroom pieces can be dried or cooked and eaten as required, though they won't be as strong as the ones in choice 2 above.

Freezing

Fry the mushroom, preferably in coconut oil, for around ten minutes on a medium heat. Cut into small pieces and freeze. Pieces can be eaten as required.

Compress

I haven't made a compress from fly agaric, so the following information is from nemf.org.

> Three small fresh pieces of mukhomor good for sore throat and cancer. Preparation for arthritis: Place several young A. Muscaria into an airtight container. Put container into a cool dark place (like a basement) until liquid comes out of mushrooms. Take a mushroom in hand, squeeze out moisture and place the pulp on arthritis. Bandage overnight. Mushroom body can be replaced in liquid and will last a long time.

Dosage

Dosage is an individual matter, varying not only from person to person, but also for the same person at different times, depending on their current neurotoxin load. The amount of muscarine (active acetylcholine chemical) present in the mushroom also varies, from one mushroom to another, and even within the same mushroom. It's best to take a small amount at a time and monitor effects.

Dried/Frozen Mushroom Pieces

It's best to start with a small amount, a piece the size of one of your little finger bones. Any benefits will be apparent within an hour. If no benefit is felt, another little finger bone sized piece can be taken. It's best to stick to a limit of three pieces this size per day.

Tincture

Rub in as much as is required to cover the target areas. If the pain or discomfort is relieved, this is likely to last for hours. Repeat as required.

Under the tongue - a few drops under the tongue. The effect will be almost immediate. Repeat as required, but don't be tempted to overdo it.

WARNINGS

Fly agaric can be fatal, though a fatal dose is in the region of 20-30 mushrooms at a time.

Large amounts of fly agaric can lead to a sense of unreality, like Alice in Wonderland. If this happens to you, don't take any mushroom for a day or two.

According to Wikipedia:

> Muscarine is contraindicated in patients with diseases that make them susceptible to

> parasympathetic stimulation, patients who have asthma or COPD or patients who have peptic ulcer disease. Also patients with an obstruction in the gastrointestinal or urinary tract are not prescribed muscarine because it will aggravate the obstruction, causing pressure to build up that may lead to perforation.

The antidote for fly agaric mushroom is milk thistle. The antidote to muscarine is atropine.

My Experience

I'd spent the whole summer lying on my boat, feeling like death, mostly too crippled to do anything, mostly too demented to see anyone.

With no memory of the past and no cognition to imagine the future, I was very much in the here and now. My butterfly brain kept settling on the colour red. Somehow this translated into me biting into a fly agaric mushroom for the first time. Just one small bite.

It tasted great. And within half an hour I had a surge of energy. It seemed as if I was doing things almost before the thought of doing them had even occurred. The headfog was clearing. It was like waking from an enchantment. It wasn't in any way "trippy" - I was simply returned to normality.

There were only a couple of weeks left until the fly agaric season was over. Every day I took a bite of mushroom and went out collecting more. Some I dried, some I froze, some I turned into tincture.

It was immediately obvious I was onto something huge, and I started writing the blog flyagarictincture.blogspot.co.uk. Prior to eating the mushroom, I couldn't read or write anything. I just didn't have the requisite cognition or attention.

There didn't seem to be any information on the web about this. All I could find was from helium.com.

> Fly agaric is still used in Siberia and Russia especially by elder people to reduce fatigue, to give more strength and to raise the spirit.

Nearly a year on and I'm still on the fly agaric pretty much every day. Just small amounts. Despite my experiments with fly agaric tincture, I now think that eating a little of the mushroom every day works best, fresh, frozen or dried. It is impossible to determine a definitive dose, as the amount of muscarine will vary from one mushroom to another. But I generally take an amount the size of a little finger bone between zero and three times a day, depending on whether I think I need it or not.

For a few months whilst on the fly agaric, I had blood tests to check my liver function. It was always fine.

Day 1 to 3

Thursday, 17 November 2011

original source: http://flyagarictincture.blogspot.com/2011/11/day-1-to-3.html

I've got chronic Lyme disease, caught from a tick bite many years ago, and it's almost impossible to get diagnosis and treatment here in the UK (and in many other countries). So people with Lyme disease either have to find a doctor who understands and can treat it (pretty much always private and also very rare and expensive), or try to treat it themselves. I've started this blog to document a treatment I'm trying: fly agaric tincture.

Chronic Lyme disease can hit your nervous system and brain really hard. It's estimated that you lose 30-50 IQ points while chronically infected (sorry, I'll try to include some links to relevant research at some point). It makes any sort of rational thought pretty much impossible. So bear with me - there's a good chance this narrative will jump all over the place.

With most treatments for Lyme disease, it's really difficult to tell whether it's working or not. Generally, if a treatment regime is having the desired effect and killing off some of the bacteria, you'll actually feel worse. This is believed to be because the bacteria as they die give off neurotoxins, which knock you for six. When a whole load of bacteria die off at once, it can produce a Herxheimer effect, first noted in syphilitic patients. This is an acute increase in symptoms, and usually lasts a few days. My first one involved nausea and an extreme thirst.

Taking the fly agaric is a completely different experience. I hasten to add, I'm just taking the fly agaric in tiny doses, nowhere near enough to get high, hallucinate or trip out. This treatment isn't about that. It's just about finding something that can either fight the bacteria, restore some quality of life, or even both.

There are many caveats with fly agaric (Amanita muscaria). In very large doses it can kill. In smaller doses it can alter your perceptions and cause you to hallucinate. In tiny doses there seems to be much less risk, but this cannot be described as a risk free treatment. I'm not suggesting anyone try this themselves. I just want to record my own experiences. Also, the amount of active chemicals in the mushrooms can vary massively, depending on the time of year, method of preparation and other unknown factors. Even two mushrooms growing side by side at the same time, prepared the same way, can result in very different levels of active chemical. This makes dosing very difficult. It seems best to start with very little.

I don't think it's possible to buy fly agaric tincture anywhere, so I realised I would need to make my own. Despite a couple of years of being completely crippled with chronic Lyme, I'm now able to walk around a bit most of the time, and was able to find four fly agaric growing wild (I'll expand on identification and collection in another post). Finding little information on the web, I decided to try several different methods of preparation and preservation.

I didn't want to wait 2-3 weeks for a tincture to be ready, so determined to chop, fry and freeze the first mushroom. I chopped another and preserved it in vinegar. I chopped another and covered it in vodka (32%-40%) to make a tincture. The last one I set air drying, intending to eventually crumble it into tea. I'll go into the actual methods in more detail in another post, and link to the articles that gave me the ideas.

PATAK'S
PATAK'S

The initial dose was a seventh of a cap, eaten with breakfast. Within half an hour I began to feel more alert and aware. I spend most of my time lying around feeling like death, but within an hour I was up and about and feeling very lively. I cycled into town and did some chores. There was no "coming up" rush, no hallucinations or change in perceptions beyond feeling lively and really up for it. It was the best day I've had in an awfully long time. Probably years. At no point did I feel any stomach cramps or nausea, possibly because of the small dose, possibly because the mushroom had been cooked.

The liveliness wore off in the late afternoon, and I did get pretty tired. I was back out for more fresh air and exercise though. Actually I went out looking for more mushrooms! This is the first treatment I'd tried that undoubtedly makes you feel better.

I mentioned this experiment on the Lyme disease forum I frequent. Within an hour of taking the first bit of mushroom, I felt I might be onto something, and wanted to let someone know, in case I was run over by a bus or something. To my astonishment, someone on the forum had ten days earlier been given a bottle of fly agaric tincture by a top herbalist, to treat the "head fog" or mental confusion that goes along with chronic Lyme. He was told to put a couple of drops under his tongue every half hour until his head felt clear. I've since found out that you can get fly agaric tincture on prescription in Germany.

I was certainly very tired that evening. I'd done a lot more physically than I normally would in a day. I slept very well that night.

Day 2 I took half the amount of fried and frozen and refried mushroom at breakfast, taking the other half of a seventh of a cap later in the afternoon. This was to try and even out the energy levels throughout the day. Again, I found I had energy and mental clarity way beyond what I've become accustomed to. The best way to describe it is that it is as if an enchantment has been lifted. The chronic fatigue aspect of Lyme seems to disappear. Last week it was a huge effort to just try and think around a simple chore, let alone do it. This week, the chores are simply done, in less time than it would normally take to try and get your head round what needs doing. It's starting to feel quite miraculous. Needless to say, I was out hunting for more mushrooms again.

I'm still not letting myself get too over-excited though. In the summer I took a month long course of Korean ginseng, to try to get some energy. The first couple of days I felt all right, but then was much worse for the rest of the summer, without a single "good day". I've since found out that ginseng can feed the energy of the bacteria and actually make you feel worse. I'm hoping that the same thing isn't true of fly agaric.

I had trouble getting off to sleep that night, and thought that perhaps I had taken too large a dose in the afternoon. It's already becoming clear that multiple tiny doses, such as tincture drops, would be a much better way of administering the fly agaric, and managing the levels you're taking.

Day 3 I took a similar amount to Day 2, but missed out the afternoon dose. I think even my small doses are possibly too large. Energy levels and mental clarity continued to be astonishing. My long-suffering boyfriend is amazed at the change in me. He even got breakfast in bed this morning.

Again I was out mushroom hunting. It's getting near the end of the season, so it makes sense to collect them now. In exchange for taking the mature mushrooms, I plant some fly agaric spore, which is found in the gills of the mature mushroom. I'll go into more detail in another post at some point.

I missed the afternoon dose but still had trouble getting to sleep. I should add, insomnia is one of the symptoms of chronic Lyme, and comes and goes. It could be unrelated to the fly agaric experiment.

I've given up the other methods of storing the mushrooms (pickling, drying and freezing). With the pickled mushroom, all the red colour was leaching into the vinegar, and I was concerned that the active chemicals might end up in the vinegar. I've also decided to dry the mushrooms for a few days before making the tincture. From my experiments so far, this should ensure a deeper red hue in the tincture. Since it was the colour that drew me to the fly agaric in the first place, this seems important.

EDIT It seems it wasn't the drying that made the colour brighter. There was an immature mushroom in one batch (it had been kicked over so I bagged it up) and the colour is much brighter before they reach maturity. I guess the tincture will end up pink, but pink is good too :).

Gathering the mushrooms and making the tincture

original source: http://flyagarictincture.blogspot.com/2011/11/gathering-mushrooms-and-making-tincture.html

Amanita muscaria is found mostly in woods, from late summer to late autumn. Mostly around birch trees, they can also be found around oak and pine. They stand out a mile, bright red, usually with white spots, unless they've been washed off by the rain.

There are real dangers if you take the wrong mushroom, so if you're not 100% sure, don't do it. Your life or liver might depend on it.

These photos are of some mushrooms I found on the common yesterday.

I've just been taking the mature ones (when they've flattened out), and returning for the immature ones a few days later, by which time they've matured. There's a frill halfway up the stem. Cut them off there, then you can air dry them without crushing the gills.

To say thank you I propagate the spore to create new colonies:

- Put caps or bits of caps that aren't good enough for medicinal purposes (if they've started to go off) into a container.
- Add water and mix or shake well.
- Pour over the roots of a birch, oak or pine tree that doesn't already have a colony.

Wrap your harvest individually in cloth. Newspaper will do, but bits of paper will probably get stuck on the mushroom.

I'm still experimenting with what to do next, but here's what I'm currently doing.

- Air dry the mushrooms for a couple of days, preferably somewhere sunny, warm and drafty.
- Clean any dirt off the mushroom once it has dried. Don't wash the mushroom. Clean the dirt off with a soft brush or your fingers. It doesn't matter if some bits are left.
- Cut into pieces around a centimeter or half-inch square.
- Put into a jar and cover with spirit that is 32-40% proof. Stop pouring when the mushrooms start to float. Within a little while the mushroom pieces will start to shrink and the spirit will take on a pink or red hue.
- Put in a warm and sunny spot for 2-3 weeks.
- Strain the liquid off. Don't force anything through the muslin or whatever.

Drying the mushrooms

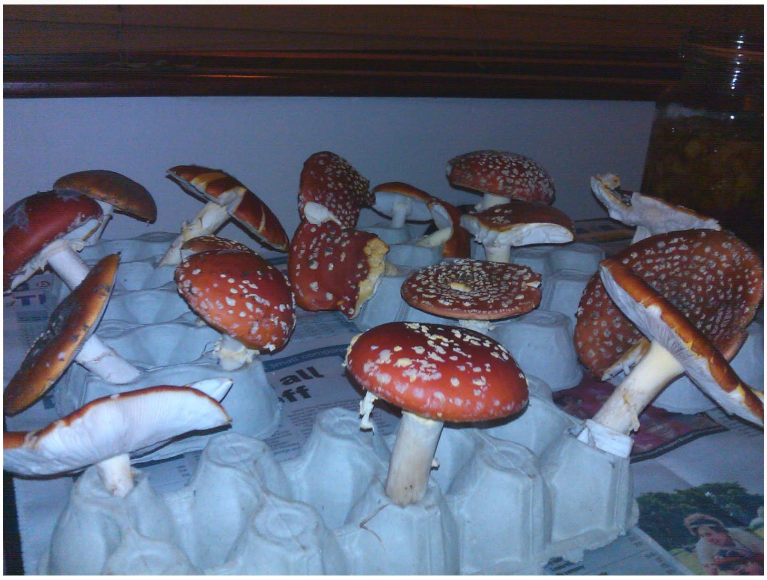
Saturday, 19 November 2011

original source: http://flyagarictincture.blogspot.com/2011/11/drying-mushrooms.html

The mushrooms I was attempting to air dry weren't really getting any drier. I picked them before realising that the gills would need a good air flow around them, and I didn't leave a stalk. Thinking about it now, I could have perched the cap on a stick to dry, but I didn't think of that at the time. We had a good fire burning, and I thought I'd give heat drying a try.

I'd read that the gills go temporarily mushy when heated, and they should be placed top up to catch and dry any goo. I put them in the ashes under the fire overnight, and they were lovely and crispy this morning. I've put them in an air-tight container and will pop a bag of desiccant in there if I can find one.

Harvesting continued today. I don't know whether the unseasonably warm weather is extending the fruiting season, but don't want to run out of these miracle working mushrooms before the next season comes around, not until the end of next summer.



I cut today's crop with their stems on, to have another go at air drying. If they're still not drying successfully, I'll fire dry them or freeze them. Stuck into holes in egg boxes, they make a little enchanted tabletop forest.

First Week Summary

Monday, 21 November 2011

original source: http://flyagarictincture.blogspot.com/2011/11/first-week-summary.html

It's now a week since I started taking very small pieces of fly agaric mushroom for my Lyme disease. I have to say, it's proving successful beyond my wildest dreams. I spoke with my LLMD (Lyme Literate Medical Doctor) at the weekend, and she expressed great interest and explained to me how it's working. And it is undoubtedly working.

The fly agaric won't actually kill any borrelia bacteria. You'll still need something else for that. But what it is doing is alleviating the symptoms that make this disease so horrible. For me, this is mostly chronic fatigue and dementia symptoms.

Up until last week, my days largely consisted of lying around feeling like death, too mentally confused to do pretty much anything. I'd stopped going out and seeing people, because I couldn't keep up with conversations, and I would sometimes say things that offended people, without realising what I was doing. Plus I had absolutely no energy.

Since starting the fly agaric experiment, it's been like breaking an enchantment. I've been describing it as a miracle, and that's exactly how it feels. Within half an hour of taking the first piece I could feel the difference.

I've been incredibly active every day. My cognition is so improved. There's no way I would have been able to string my thoughts together in a blog like this before. Friends and family have mentioned how much better I am, and that I have a sparkle back in my eyes. I really feel like myself again. I haven't been able to work for four years (I was a computing lecturer), but I feel now that I could certainly do something, and I don't feel hugely far off lecturing again, once I get my stamina and full mental ability back.

Fly agaric is still used in this way - ingesting small daily pieces to treat psycho-physical fatigue and more - in remote areas of Siberia. I haven't found anything new, just something that has been forgotten by our culture. Not a cure, but a treatment for chronic fatigue, dementia and more (possibly Parkinsons, schizophrenia and more). It's also great as a painkiller, and I no longer use my previous method of pain control. The mushroom is enough.

Here's a bit of science, but I don't pretend to understand it, so if I've made an error - or if you can explain it better - please let me know via email or comments. It seems that neurotoxins (from the bacteria dying off) clog up the muscarinic receptors (which are acetylcholine receptors), and messages contained in neurotransmitters can't get across. A chemical in the fly agaric mushroom forces these messages across, and hey presto, suddenly you can move and think again.

Of course, just because this treatment is working for me doesn't mean it will work for everyone. Lyme disease can present very differently in different people. And there are dangers involved, either through picking the wrong mushroom or taking too much.

Once my tincture is ready, in another week or two, I'll be moving onto that, but until then I'll continue harvesting (the season end is drawing near) and eating a little cooked and frozen mushroom every day. Someone very dear to me has early stage dementia, and I intend trying to get them to take it. And a good friend has bad back pain, and I'll try her with the tincture drops once they're ready. For back pain, apparently you can just put a few drops on the site of pain - no need to ingest it - so it'll be interesting to see what happens there.

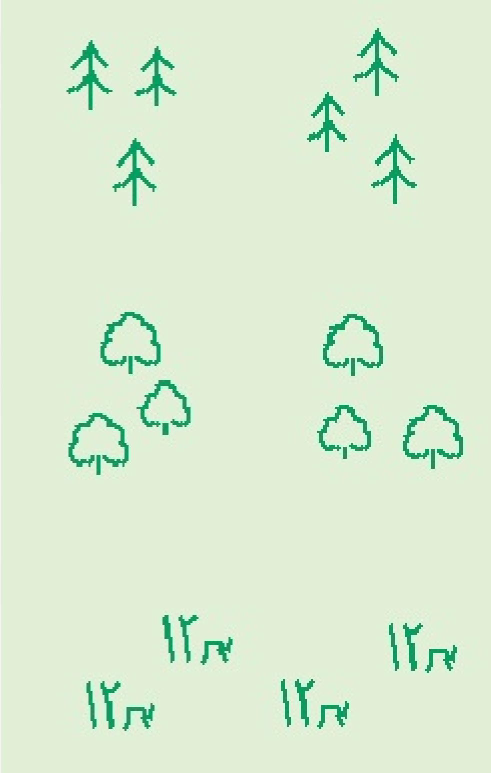
Ten Things I Learned This Week

Thursday, 24 November 2011

original source: http://flyagarictincture.blogspot.com/2011/11/ten-things-i-learned-this-week.html

Everything's still going well, ten days into the treatment of Lyme disease with very small amounts of fly agaric. I'm still eating bits that have been cooked and frozen, as the tincture isn't ready yet.

1. *Image (below) from top: coniferous, deciduous and coppiced woodland. Some woodland is a mix of these types, in which case there will be a combination of symbols.*
   The easiest way to find woodland to search for fly agaric is to look at a local Ordnance Survey map.
   Although the fly agaric mycelium can be hosted by pine and fir, these forests, in Britain at least, are more likely to have been relatively recently planted for timber, and unlikely to harbour any Amanita muscaria.
   Coppiced woodland is likely to be hazel, willow, sweet chestnut, hornbeam or alder, none of which host the symbiont, so are probably not worth hunting in.



2. I've stopped wrapping the individual mushrooms in newspaper, as it was sticking to the tops of the caps. A basket or cloth bag is a better bet.

3. The stalks are likely to contain maggots. I left the stalks on the mushrooms I was air drying, which resulted in more than a hundred tiny maggots wriggling around on the coffee table. Luckily I removed them before my boyfriend spotted them! From now on I'll either leave the stalks in the ground or use them to spawn with.

4. When spawning I've found that if you dig (just with a small stick) around the base of a host tree (birch, oak, pine, fir), ready-made fissures can appear. The idea is to get the spore on the roots, so I've started making use of these fissures. I've also put pieces of mushroom into animal burrows that lead under a potential host tree.

5. The best way to remove bits of dirt from the mushroom cap is with a mush brush, a special soft brush for cleaning mushrooms without damaging their skins.

I've ordered one but it hasn't come yet. I'll review it when it does. I'm hoping that it will work on damp mushrooms as well as dry ones.

6. Drying the mushrooms can cause an allergic reaction. I was pulling the stalks off the mushrooms I've been air drying, and my nose started running. My nasal membranes were sore for quite a while. I don't think I'm going to air dry again.
7. An alternative to air drying is to use a food dehydrator. If I weren't able to take the tincture - if I had an allergy to alcohol for example - I might consider this route.
8. I started on a new mushroom from the freezer this week. I took a piece the same size that I had from the previous mushroom, but became very clumsy. I think that the new mushroom has more active ingredient. I've been taking smaller pieces since, and everything has been fine again.
9. All things considered, I think I will clean, chop and tincturise the mushrooms right away from now on. As well as avoiding drying allergy, it will also make the strength easier to determine, by averaging out the strength of all the mushrooms in the vodka.
10. It's best to shake the jar with the mushrooms in before adding the vodka. This helps them settle, and you can fit more mushrooms in the jar.

Week Two Summary

Monday, 28 November 2011

original source: http://flyagarictincture.blogspot.com/2011/11/week-two-summary.html

I've been taking very small amounts of fly agaric tincture to treat my Lyme disease for two weeks now. For this update I'm going to list my individual symptoms and explain how the mushroom has affected each one.

1. **Exhaustion/Chronic Fatigue -** Before I started taking the mushroom, it was extremely difficult to do anything but lie around without the slightest energy to do anything. It would take the hugest effort of will to do the slightest thing.
   This changed within half an hour of taking the mushroom for the first time, and has improved ever since. I've been so lively the last two weeks, and am up and doing something almost before I've thought about it. This turnaround seems to me, and those that know me, nothing short of miraculous.

2. **Cognition -** Before starting on the mushroom, my cognition had deteriorated to such a degree that I couldn't get my head round anything. If I had to do something, or think about something, that required more than one step, I couldn't do it. I couldn't string my thoughts together to write anything. I couldn't compare or summarise anything. My IQ must have dropped a huge number of points.
   Since taking the mushroom, this is the other major area that has seemed miraculous. The difference is huge, and my cognition is still improving. I've been able to pick up my work developing mobile phone apps, which I'd had to give up several months ago because my brain simply wasn't working. I can keep up with conversations again. I'm able to formulate my thoughts enough to write this blog.

3. **Memory -** Prior to the mushrooms, my memory was shot. This is related to cognition, above, and together they make up the majority of the "dementia-like symptoms" that you get with Lyme disease.
   It seems that some medication aimed at treating dementia uses the same mechanism as the fly agaric tincture, for example:

   > Piracetam improves the function of the neurotransmitter acetylcholine via muscarinic cholinergic (ACh) receptors which are implicated in memory processes. (from Wikipedia)

   Needless to say, my memory is greatly improved now. I no longer have to carry a list round with me detailing anything that I'd need to do that day (assuming I'd remember to write it down in the first place, not lose the list, or forget the list even existed). I'm almost able to take my memory for granted again.

4. **Loss of Control** - The other main "dementia-like" symptom is very creepy, and involves seemingly losing autonomic control over your actions, and doing and saying things you really didn't intend to.
   I haven't lost control and done or said anything inappropriate since I started on the mushrooms. This was the main reason I had stopped socialising (as well as the chronic fatigue), as I was terrified I would say something that offended someone, and this did happen a couple of times. It's such a relief to be free of this.

5. **Stamina** - Prior to the mushroom, I could do little chores like housework for five or ten minutes at a time, then would need to rest for at least five or ten minutes. My muscle and tendon trouble would mean that I couldn't be on my feet for very long anyway.
   Yesterday I walked for around five miles, with barely a rest. This is far and away the furthest I've walked in four and a half years, since my life fell apart with what turned out to be Lyme disease. I was tired afterwards, but managed to watch a football match on TV and then cook and eat a roast pork dinner before dropping off for an hour's nap.
   It's probable that fly agaric is the Viking berserker mushroom that would give them such amazing stamina, so it's not surprising that it does improve stamina. I'm really getting a full day every day now.

6. **Pain** - An old injury in my neck, back and shoulder had caused me to need pain relief every day. This injury seems to have been colonised by the borrelia bacteria, as they can use your own collagen to build citadels for themselves in areas that are low in movement or oxygen. This is why with Lyme disease it's so important to keep moving and stretching your muscles, even if you're just lying there.
   Although I do still have low levels of pain and discomfort, I no longer require any pain relief at all.

7. **Muscle ache** - When exerting my muscles in any way, such as climbing the stairs, they would ache quite terribly. I still get this to some degree, but it is improved and improving.

8. **Tendinitis -** It was tendinitis in my ankles that started this health nightmare that eventually turned out to be Lyme disease. After two years of only being able to walk a few steps, this did improve with deep tissue massage, but was still a great limiter in what I've been able to do. The tendinitis would flare up, mostly in my ankles and knees, just about every month, when the bacteria have their monthly bloom. A bad flare would take weeks to get better. I had tendinitis in my ankles all summer this year, and could barely do anything.
   With all the extra exercise I've been getting since starting on the mushroom, I had a flare of tendinitis at the back of my knees last week. I expected it to last a few weeks as usual, but it was gone within a few days on the mushrooms.

9. **Hypocapnia/Hypocapnoea** (low carbon dioxide, causing nausea, dizziness, seizure, muscle spasm) - I'm not sure whether the mushroom is just improving the symptoms of this, or whether it's addressing my low carbon dioxide levels. I haven't had as much dizziness and muscle spasm, I've had no nausea, and it's much more rarely that I realise I'm not breathing.

10. **Cold -** My body does seem able to regulate its heat better. I'm sure the increase in activity must help with this. My temperature has been 35-36C before the mushrooms, but often at 37C since.

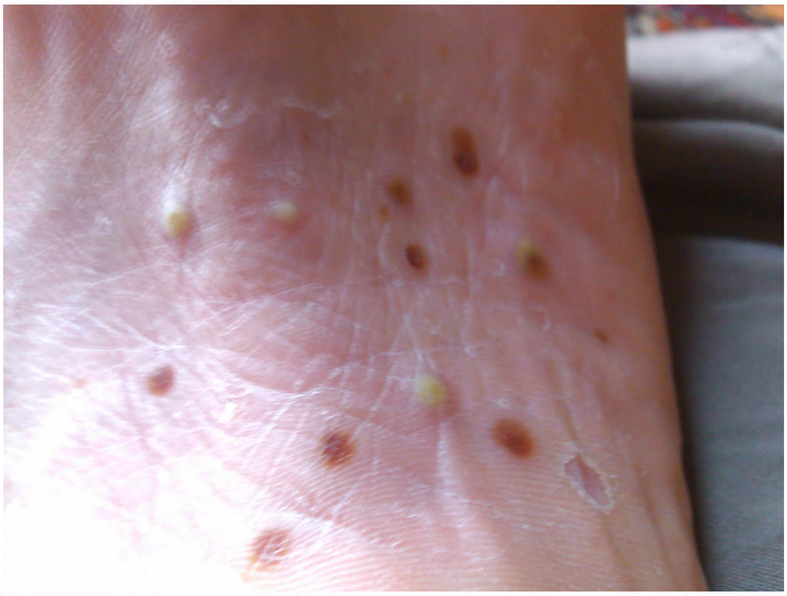
11. **Insomnia** - I haven't had any episodes of insomnia over the last week, though I did have a couple the week before.

12. **Tinnitus** - The tinnitus was very variable before starting on the mushrooms, so it's hard to say whether this has been affected. It hasn't been bad over the last week though.

13. **Tourettes-like moments** - When I remember something embarrassing I've said or done, a strange uncontrollable noise will erupt from me. I understand this is also related to Lyme disease. I've only had it over the last few years, during which the Lyme wrecked my life. I haven't had this as much over the last couple of weeks, but it does still occur every few days or so.

14. **Stress and worry** - My levels of stress and worry have gone way down since starting the fly agaric. I'm sure this must have a positive effect of many of my other symptoms as well. I honestly can't think of a time in my life when I've felt happier and less worried. The simple joy of being alive, and the beauty and draw of nature, are making my life a living paradise.

15. **Antibiotic Effect? -** I have had something on the sole of my left foot for probably two years now. I've been told variously that it's verrucas and athlete's foot, and treated it accordingly, but it's made no difference. Rubbing raw garlic into it would get rid of it briefly, but it always came back. My LLMD (Lyme Literate Medical Doctor) said that she thought it was bacterial. Since I started on the fly agaric a couple of weeks ago, the infection has almost gone.



16. **Sensitivity to Light** - I still have great sensitivity to light, especially when unexpectedly reflected.

I've tried to be as objective in this write-up as possible. I should add, this isn't the first treatment I've tried that I thought would work, so it can't be explained by a placebo effect. I really think I've stumbled onto something of immense value here, something that was once known but has been forgotten, except in some remote areas of Siberia.

I'm only two weeks into this experiment, so it's possible of course that difficulties may yet arise, but after two weeks, small pieces of fly agaric are having a seemingly miraculous effect on almost all my symptoms.

Photos on this post are from sxc.hu, a free photo site (except for the foot rot).

I appreciate reading such positive things about this mushroom!!! This has always been my Mum‘s favorite mushroom. Not to take medicinally but have a creative fascination with. She learned a great respect for it at an early age. She comes from a rural part of Latvia where the mushroom is known and used by native healers. She spent a great deal of time with a grandmother who was such a healer. They gathered such mushrooms but she doesn't recall exactly what it's use was. She knows it was greatly respected, which is partly where her own fascination began. Thank you so much for sharing your experience!

Dace, thanks so much for letting us know! I think I'd very much like to travel where healers are using fly agaric. It's wonderful to know that this knowledge lives on in some places. Full respect to rural Latvia x

Hello all - I have been taking tiny bits of the dry mushroom (say 1/4 " square sz, or a bit more for only four days.
I hesitate to post so early, but indeed both me and my husband feel a slight shift in attitude.
For the better! Slight mood enhancement and clarity - more positive.
We have had much reason for situational depression for several years now - so this change is phenomenal for us both.
I think of the literature I read about "elder folk" using the fly agaric in some cultures.
Would heed the warning of Henrietta's herb page - esp. if taking antibiotics - Agaric is very hard on the liver. Take good care!! MB

mb - that's fantastic! Long may it continue! Thanks for letting us know, and do keep us posted on how it goes.

Many thanks for this! I still have the infection so I'll see what I can do. Thanks for taking the time to let me know - I really appreciate it.

Finishing the Tincture

Saturday, 3 December 2011

original source: http://flyagarictincture.blogspot.com/2011/12/finishing-tincture.html

1. The chopped mushrooms have been soaking in vodka for 10-14 days now, so it's time to strain them and complete the tincture. The colour in the jar doesn't really show here, but it's a beautiful golden red.

It's been sitting in the sun for this time, as this is the advice for most tinctures, but it may well be that it would be better in the dark. I really don't know. The liquid is really clear though and smells good too.

2. The contents of the jar need straining first. I've borrowed my boyfriend's muslin cloth that he uses for wine making, but an old pair of tights would probably work just as well.

I've just left this to strain for an hour. I'm not sure whether to squeeze the mushrooms and get every last little drip out of them. I just let them drain with the first couple of batches, then put the mushrooms in the composter. But now the harvesting season's at an end and there's a finite supply, I've given these ones a good squeeze.

I'm going to save the squeezed mushrooms to try and cultivate the mycelium. More on that in a later post, fingers crossed!

3. I then run the liquid through a coffee filter. As you can see in the image of the completed jar (below), there is some white stuff that accumulates at the top of the jar. I think that this is the mushroom spore, which is definitely white, and small enough to get through the coffee filter.

The liquid itself is a gorgeous reddy golden amber colour.

Mushroom spore shell is made of the hardest yet lightest natural substance we know of. People such as Terence McKenna have posited that it's light enough for the spore to be blown anywhere on the planet, even into the upper atmosphere.

It is then hard enough to survive being sucked through the atmosphere and can be blown across the empty vast distances of space, perhaps eventually being sucked into another planet's gravitational pull, and forming a new colony in an alien land.

4. The tincture is then decanted into bottles. It's a good idea to label these to show what they contain, and with a warning that the contents are poisonous (if taken in excess).

I bought some stickers from eBay for this, some nice shiny fly agarics to show the contents, and some skulls to warn poison. The skulls however are from Nightmare Before Christmas, and look unbelievably cute. Best to keep out of reach of children. And teenagers.

Hey nice post! I discovered Fly Agaric about three years ago, and have been experimenting with it ever since. I have been taking subliminal amounts almost daily (dried stem pieces mostly) as well as occasionally cooking with it (smallish amount in an omelette in the morning) and eating larger amounts of the dried mushroom. This year I ate a small piece (size of a fingernail) while out mushie hunting. I didn't read your whole post and I am wondering if you tincture fresh or dry? The effect will vary in each case. Generally dried or cooked mushrooms are preferred over fresh (not just for the F. Agaric, but most mushrooms in general). This mushroom, although it has a reputation as a poison (mostly based on ignorance and fear, I'm afraid) which it doesn't actually live up to. It IS poisonous to smaller animals, like insects, and seems to have antibiotic properties as well (I use it as a general antibiotic in the winter to keep healthy, always alternating with probiotics of course). The only people who have ever died or gotten deadly sick from this mushrooms are those who have eaten an absurd amount of fresh mushroom deliberately (suicide attempts?). It will make you throw up if you eat an amount of fresh ones, but alot of mushrooms act this way... My personal opinion is that this was probably the first antibiotic medicine used by humans. It is easy to find, hard to miss, and impossible to confuse with another mushroom! I would even risk saying that it may be a good antibiotic for actually killing the life-form which causes lymes disease.... Why take expensive anti-biotics when you can go out into the forest and gather turkey tail and amanita musc.? It's just a thought... Glad that you are doing research on this wonderful medicinal mushroom! I'll read the rest of your blog when I have more time! Cheers!

Sam Malone *4 January 2012 at 04:25*
Thanks for your comment. I'd be interested to hear more about your experiences.
I experimented with making the tincture out of both dried and fresh mushrooms. I had a steep learning curve, and initially thought that it would be the muscimol I was using, so dried the mushrooms to ensure as much ibotenic acid as possible was converted to muscimol.
It now seems it's the muscarine that's really helping, though the other chemicals are probably helping, and, as you say, the antibiotic properties. I've read that fly agaric have antibacterial, antiviral, antiparasitic and antifungal properties as well.
It also makes a good plug-in immune system for oak. I'm really hoping it'll protect them against the apparently bacterial acute oak decline.
From now on I'll make the tincture with fresh mushrooms, including the stems. It seems to taste a lot better with fresh mushrooms (especially when using green apple vodka for the tincture).
Great to find someone doing something so similar! Best wishes, Sam

Hi Sam,
Thanks for your interesting blog. I came upon it through a link from your post in the Telegraph online regarding Dr Sarah McKenzie Ross' research about organophosphates exposure, which I'd googled, having just heard her on Radio 4 today.
I was interested because my partner has recently been diagnosed with Primary Progressive Multiple Sclerosis, (which, as you may know, is an auto-immune disease affecting the myelin sheath, which insulates the nerves and helps in the transmission of nerve impulses between the brain and body) or at least, that's what the neurologists think it is. He is, or was, a farmer, all his life from a long line of farmers, so very likely has used these chemicals. MS is, of course, not the same as Lyme Disease but some of his symptoms appear to be similar to those caused, apparently by OP exposure, but also to those of Lyme Disease, (and probably to lots of others) though he is now severely disabled, barely able to walk, slow speech, constantly dizzy, fatigued, suffers tremours, memory problems, etc etc and is literally half the man he was as his muscles have deteriorated. There is, so far, no cure for MS, and he hasn't been offered any treatment, although there are treatments but only for the less severe types and not cures but merely to slow the progression.
The point of my post here - and I apologise for being long-winded - I realise the causes may differ, and while I'm not suggesting Fly Agaric could necessarily help him, but I was wondering if, along your research trail, you had ever come across anything covering MS, or rather, anyone using 'alternative' methods for treating the symptoms, as you are with Lyme and Fly Agaric.
While I am no scientist I don't believe anything without hard evidence, but I do believe these old remedies are often dismissed in modern times (at least, in the West) and deserve more respect and credence considering their efficacy has been 'field-trialled' over thousands of years, and indeed, currently, by yourself. I am also a cynic, however, and I certainly do believe the likes of Pfizer, Bayer and Monsanto are unlikely to support my beliefs, at least not without slapping on a patent, any time soon.
Warm Regards
Sue Phipps

Hi Sue and so sorry to hear about your husband.
Actually in Siberia (and possibly further afield) they use fly agaric to treat MS! MS and Lyme are so similar, to the extent that a large number of people diagnosed with MS later find out that they actually have Lyme. I'll happily send you some fly agaric to try. It's probably easier to email me at crowcity@gmail.com
Have you heard about Dr Wheldon's explorations and experiments when his wife was diagnosed with MS? http://www.davidwheldon.co.uk/ms-treatment1.html

Week Three Summary (Getting the Dosage Right)

Sunday, 4 December 2011

original source: http://flyagarictincture.blogspot.com/2011/12/week-three-summary-getting-dosage-right.html

Week 3 has been good. I've continued to be active both physically and mentally, and have had no insomnia. In fact my confidence has been such that I've broken a little from the no alcohol, no dairy and no gluten diet I've been on since February.

The only trouble I've had is getting the tincture dosage right, and this has definitely affected my perception here and there.

The fly agaric tincture has matured now, after sitting in the sun for 10-14 days covered in vodka. So this week I stopped eating small pieces of frozen cooked mushroom and started on the tincture. The changeover hasn't been as easy as I'd expected. The tincture is much stronger than I thought.

I'm currently taking various other tinctures to help with the symptoms and cause of Lyme disease - Banderol, Cumanda, Milk Thistle, St John's Wort and Sarsparilla. I'm also on a month-long anti-parasitic regime of tinctures of Wormwood, Clove and Black Walnut Hull. The dosage for these tinctures is generally around 10 drops 3 times a day, so I decided to start with that amount of fly agaric. That proved to be a mistake.

I was taking way too much fly agaric tincture. I was actually getting some of the effects typical of "vision questing" with it, without intending to. I didn't realise this, as the overall effect can be quite similar to Lyme symptoms (drowsiness, blurry vision, a sense of timelessness, distancing or separateness from what is generally considered to be reality, a lack of insight into some things, a little macropsia/micropsia - things becoming big or small).

I've never taken fly agaric for any purpose other than in these very small quantities for treating the Lyme symptoms these last few weeks, so I didn't know what it would be like to take it in larger quantities. It wasn't scary or anything (it removes fear anyway, one of the reasons why warriors such as berserkers would go into battle on small amounts!), but it must have altered my perceptions to some degree, as I simply wasn't aware that I was taking too much.

In other words, I don't think you can rely on your perception to get the dosage right. I think it's better to go with the numbers, and keep the dosage really small. Just enough to oil the processes of thought, memory and movement. Like oiling a squeaky door or a machine with moving parts, just a drop here and there.

A gentleman on the Lyme forum I frequent is also taking fly agaric tincture for Lyme, given him by a qualified herbalist. He has been on the tincture for a few weeks now, and has found that 2 drops 3 times a day works best for him. I'm going to follow his advice this week, and stick to that. I've also decided to take one day off from it a week. To this end I took none today, and had plenty of energy and felt bright mentally all day.

Tradition of Using Fly Agaric Medicinally

Monday, 5 December 2011

original source: http://flyagarictincture.blogspot.com/2011/12/tradition-of-using-fly-agaric.html

Here are the only mentions I've been able to find on the net of using fly agaric in small medicinal doses. Mind, Google would have only returned sites written in English. If you are aware of any others, please add them in comments.

> The Koryaks use this mushroom in a variety of ways, including administering it to their old people to insure their sleep at night and their energy during the day. Tatiana, the Even shaman, uses this mushroom externally as a poultice to treat patient wounds, as an anti-inflammatory and analgesic, and internally (by herself) as a device to allow her to visit the spirit world to seek, for example, the cure for an illness (physical, mental, or spiritual), or the place where a successful hunt could occur.

Occasionally they were mixed with the juice of Willow-Herb. No research is known to have investigated the possible synergistic action of this combination. Medicinally it was used for 'psychophysical fatigue' and for bites of venomous snakes (Saar, 1991). It was also applied externally to treat joint ailments (Moskalenko, 1987). In Afghanistan a fly agaric smoking mixture known as tshashm baskon ('eye opener') is used for psychosis (Mochtar & Geerken, 1979). In Western medicine Fly Agaric serves as a well known homeopathic remedy, used for tics, epilepsy and depression, and in conjunction with homeopathic Mandrake tincture, is used to treat Parkinson disease (Villers & Thümen 1893, Waldschmidt 1992).

Looking beyond the net for information, perhaps we can turn to the less rational archive of myth and fairy tales. It's possible that knowledge has been encoded in these.

For example, I recently found out that a folk name for fly agaric is "raven's bread". And who are the only two ravens that most people could name? Huginn and Muninn, literally Thought and Memory, who sat on Odin's shoulders and whispered in his ears when he needed to know something.

This struck me as being perhaps more than coincidence, since improving thought and memory are two of the main benefits of eating raven's bread in small raven-like quantities, medicinally.

Advice for an Imaginary Test Subject

Friday, 9 December 2011

original source: http://flyagarictincture.blogspot.com/2011/12/advice-for-imaginary-test-subject.html

Of course, for legal and safety reasons I can't recommend anyone try taking fly agaric tincture, especially without medical supervision. But if someone were to decide to try taking small amounts of fly agaric tincture to see if it might help alleviate symptoms of Lyme disease such as dementia and chronic fatigue, my advice would run something like this...

The Tincture

- The tincture is really strong. It will affect you in ways that other tinctures don't.
- Taking a higher dose of the tincture won't do you more good, or make you feel better than small doses. Small doses work best.
- If you have physical pain somewhere, you can rub a few drops into the skin where the pain is (back etc). I'm not sure whether you should include these drops in your daily total. It's possible that active chemicals are absorbed through the skin.
- You may notice something white floating in the tincture. I think it's the mushroom spore, which is so tiny it gets through the coffee filter. It won't do you any harm. It can't grow inside you.

Taking the Tincture

- Take 1-3 drops 3 times a day (early morning, late morning, late afternoon). Probably best to start with 1 drop first day, 2 drops second day etc. Be really careful about going higher than 3 drops at a time. Even

3 may be too many for some people.
- Take the drops under your tongue or in a cup of tea or however you like.
- You can manage your energy levels by overlapping the times when you take the drops.
- Take a day off the drops a week. This way you can still monitor your symptoms. The tincture may alleviate your symptoms, but the infection is still there in the background. Even if you're feeling much better, you still need to address the underlying infection.

Results of Taking the Tincture

- The effects of the drops last 4-6 hours, although some benefits do seem to go over to the next day.
- You may suddenly find you have huge amounts of mental and physical energy for the first time in years. Be careful to pace yourself and remember to stop and stretch regularly.
- If you take much more than 3 drops at a time, you may "trip" a bit. These effects are likely to be sleepiness, mild euphoria, blurred vision and micropsia/macropsia (things suddenly seeming much bigger or smaller than they actually are). You may not notice that this is happening to you, as your insight may also be affected. Ask someone to keep an eye on you, or put up signs to remind yourself that this may happen. You are best just keeping to very small doses. Larger ones won't give a greater benefit.

Safety

- The dose may be quite particular to each individual. Whilst you're working out the right dose for you, don't drive or operate machinery.
- Treat your bottle of fly agaric tincture as poison. Label it accordingly and keep out of reach of children. And curious teenagers!
- As with any psycho-active substance, there's a very small chance of psychosis from taking the fly agaric tincture. If this happens, stop taking the tincture and everything should go back to normal. If it doesn't, tell a medical professional that you have been taking fly agaric tincture to stimulate your muscarinic receptors because of your Lyme disease. They will give you something to counteract this.
- Take milk thistle in some form. This is the antidote to fly agaric tincture and will help protect your liver. The tincture will still work just as well.

Happy Holidays. I have purchased some caps.
What proportion of alcohol to mushroom did you use for your tincture? Or did you just pour until rooms were covered. I looked at Henrietta's - but would like to hear from you as you are having success.

Sam Malone *29 December 2011 at 10:18*
Hi mb
Are your caps dried? If so I'd probably rehydrate them before adding the alcohol. Chop and add a little water and wait until they're rehydrated. I've never tried this but am thinking of doing it with some of the ones I dried, so let me know how it goes!
Yes I just covered the mushrooms with alcohol. I read somewhere that you need to use 36-40% alcohol, nothing stronger.
I found that it's best to chop into smallish pieces (about half an inch or 2cm square), put into a jar, shake the jar then cover with alcohol.
Leave for 7-10 days then strain through muslin if you've lots of mushrooms, or just a coffee filter if you don't have so many. I'd always strain through a coffee filter after the muslin. The spore will still get through though, and rise to the surface if left overnight.
Let us know how it goes!
Best wishes,
Sam

Week Four Summary

Monday, 12 December 2011

original source: http://flyagarictincture.blogspot.com/2011/12/week-four-summary.html

I've now been taking very small amounts of fly agaric mushroom daily for four weeks, in an experiment to see if and how it might relieve some of the symptoms of my chronic Lyme disease (neuroborreliosis). This post will summarise the whole first month, as well as Week Four.

The first two weeks I was eating small pieces of frozen mushroom, around the size of my last little finger bone. Once the tincture was ready I moved over to that, finally settling on a dose of 1-3 drops 3 times a day. This is usually 3 drops when I get up, 3 drops late morning and 3 more drops late afternoon.

The mushroom has had an amazing effect on me over the last month. My chronic fatigue, poor cognition and dementia are so much improved, I really feel like myself again. I can walk for miles, read and evaluate what I've read, keep up with conversations and enjoy being with people again. It really has been nothing short of miraculous.

Even during Week Four, my physical and mental faculties have continued to improve. I'm now reading five books at a time, devouring the information contained within them, remembering every word. A month ago I couldn't read at all, as I didn't have the cognition to figure out what was being said, or the memory to build meaning. Yesterday I ran for a few hundred yards. During most of the summer I couldn't walk even 50 metres.

Before I became disabled and my life fell apart (four and a half years ago), I worked as a computing lecturer. For the first time since then, I feel I'm not far off being able to lecture again. In the last couple of weeks I've picked up my work developing mobile phone apps, which I'd had to stop in early summer, as my brain just wasn't functioning.

There is no mystery to how this works. As I understand it (albeit perhaps incorrectly) the borrelia bacteria produce neurotoxins that congregate in the brain stem. There they block signals in the acetylcholine receptors, causing symptoms such as chronic fatigue and dementia. The muscarine in the fly agaric enables the signals to get across, overcoming the blocking effect of the neurotoxins. Hey presto, you can think, walk and live again.

I'm not claiming that fly agaric is a cure for Lyme disease or any other condition. But it certainly seems to have huge value in treating the worst symptoms. I've read that it also has anti-microbial properties, so perhaps using it longterm might reveal further benefits. Right now, you would have to prise it out of my cold dead hands to get it off me.

Yesterday I started on heavy duty antibiotics, which seems to be the only treatment that can seriously reduce the amount of borrelia bacteria infesting someone with Lyme disease. I shall continue to take the fly agaric though, to counteract the worst symptoms, and see what it can do. If I do stop taking it for a day, I do start to go back to being a zombie again. The plan is to have one day off a week though, to monitor remaining Lyme symptoms without the influence of the fly agaric.

Week Five Summary: Starting Antibiotics

Tuesday, 20 December 2011

original source: http://flyagarictincture.blogspot.com/2011/12/week-five-summary-starting-antibiotics.html

I was finally diagnosed with neuroborreliosis (late stage Lyme disease) a few weeks ago, after at least sixteen years of infection, and four and a half years of total debilitation. I was prescribed strong antibiotics (500mg of cefuroxime twice a day), which I finally started taking last week. I'd held off from taking them in order to figure the right fly agaric tincture dosage, but it seems now that this is much more variable than I had realised.

Borrelia burgdorferi, the spirochete that causes Lyme Disease. FA stain (CDC)

It took a few days of the antibiotics before I realised that I was mentally and physically deteriorating. Unfortunately with Lyme disease, insight often goes out of the window. There have been times when I've declared how much better I'm feeling, only to find out later that I'd just temporarily lost what little insight I do have. So much of Lyme disease is trying to cope with a substantially diminished mental and physical arsenal. You can have all the will in the world though, and it doesn't make a huge amount of difference. It really is like a fairytale enchantment.

The antibiotics kill off more borrelia bacteria, which creates more neurotoxins, which find their way to your brain and clog up the neurones in the brain stem. This is what leads to symptoms such as chronic fatigue and dementia.

By the weekend I decided to try 3 drops of the fly agaric tincture in every cup of tea I drank. Not very scientific, but easy to remember. It really helped. I got some good exercise both days, and was able to cope with everything I had to do.

Yesterday I went back to 3 drops times a day, and was so exhausted by the evening that I pretty much couldn't even think. A good night's sleep though, and I'm feeling better again this morning. I'll stick to 3 drops in every cup of tea for a while, especially with Christmas and the extra energy needed for that.

I did manage to publish an app for the first time since about March, when I started treating the Lyme disease, and the neurotoxins must have started really building up. So I'm incredibly grateful to the fly agaric for giving me this level of improvement.

It's scary being back in the dusty void of Lyme disease dementia. It took some courage to start on the antibiotics, as I knew that there was a chance everything would go foggy and I'd end up a zombie again. When I first took antibiotics for the Lyme, back in February/March when I presented with an erythema migrans rash, the dementia hit me like a cattle stun gun, and hasn't really cleared since. At least with the fly agaric tincture, I stand a chance of bringing myself out of it to some degree by increasing the dose.

On the forum I frequent, some people are doing essentially the same thing with nicotine patches. Nicotine acts the same way as the muscarine in the fly agaric, stimulating the acetylcholine receptors in the brain stem so that messages can get through. It seems that with that also, dosage is a very individual thing.

Week Seven Summary: External Application of the Tincture

Thursday, 5 January 2012

original source: http://flyagarictincture.blogspot.com/2012/01/week-seven-summary-external-application.html

I unfortunately missed the Week Six Summary, due to Christmas and a killer migraine that took the better part of a week to clear. I eased up my militant no alcohol, no dairy, no gluten diet in the run-up to Christmas. I've a lot to celebrate this year (found out what had wrecked my life, found a doctor to treat it, despite the usual nightmares with the NHS and Lyme), and felt like cutting loose a bit. Plus I've felt like death for most of the year, so feeling substantially better on the mushrooms, I thought I'd celebrate that too. My boils and impetigo all came back, but have largely gone now since giving up the dairy, alcohol and gluten again.

I'm actually halfway through Week Eight now, and settling into a good routine. Since the amount of fly agaric required seems to vary so much, probably due to the varying amount of bacteria and neurotoxins, I've changed my attitude to dosage. Instead of trying to find my perfect dosage, I now just take three drops under the tongue when I feel my cognition waning, which is generally every couple of hours.

I've had a lot more bacteria die-off, due to being on antibiotics now, and also freeing up the areas in my jaw/neck/shoulder/back/pelvis that are stuck together with what I believe are borrelia colonies. They crack and crunch and spike you like crazy, but bit by bit become softer and more free. Sometimes there's a big movement, and suddenly I can move a part of my body again. I actually wiggle when I walk again now, instead of moving like a robot.

As well as stretching, movement, deep tissue massage and ultrasound, I've now found something else that really helps the pain and discomfort in areas colonised by the borrelia bacteria ... the external application of fly agaric tincture!

I've a lot to say about both migraine and general external application of the tincture, so I'll break this post up into one covering migraine, and another covering external application of fly agaric tincture for sciatica and similar pain.

I should add, my experiences on fly agaric tincture may be closely related to the species of borrelia I have.

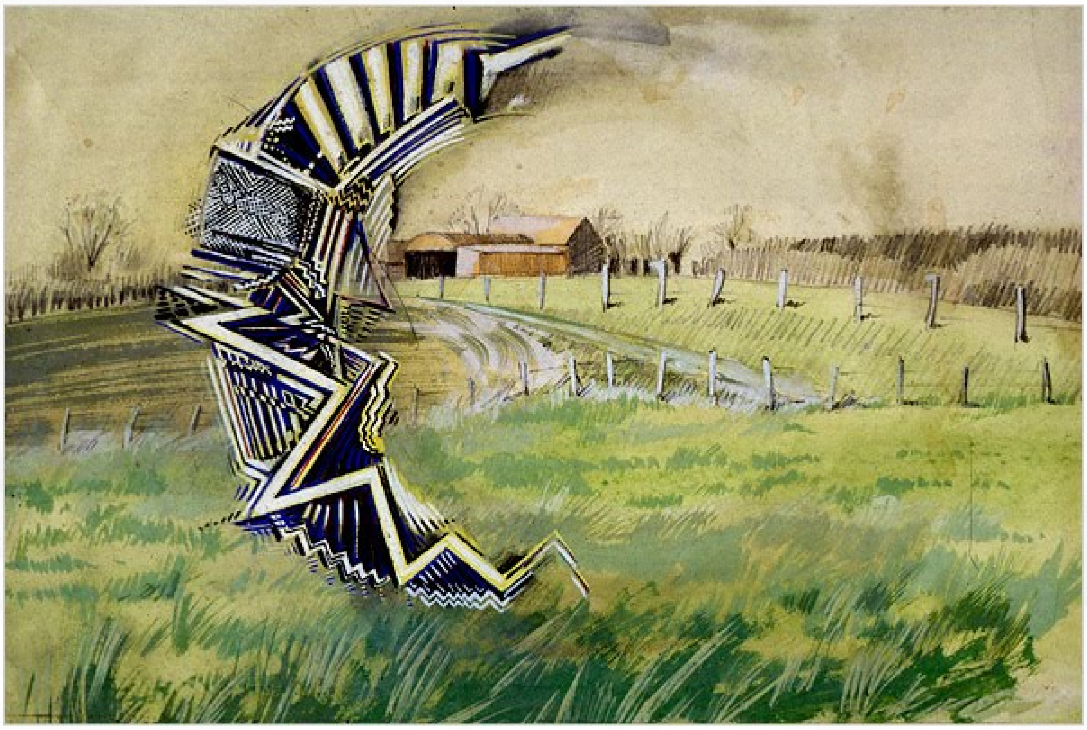
According to a Melisa LTT test, I am infected with *Borrelia afzelii* and *Borrelia garinii*. Afzelii tends to affect the nervous system the most, and garinii tends to favour connective tissue, especially tendons.

Migraine and Fly Agaric Tincture

Thursday, 5 January 2012

original source: http://flyagarictincture.blogspot.com/2012/01/migraine-and-fly-agaric-tincture.html

I was plagued with migraines during the time when I was completely disabled with tendon trouble, but had no idea that it was late stage Lyme that was the cause. The migraines would generally appear the day after I'd had a session stretching my neck. Again, I didn't realise it at the time, but the borrelia bacteria had colonised my neck, and the stretching and manipulation were breaking some of these colonies up, releasing large numbers of bacteria or associated neurotoxin detritus. I assume it was this that caused the migraines.



I did a whole diet exclusion course to be sure that it wasn't anything I was eating that was causing the migraines. I excluded everything that had ever been believed to have even only possibly caused a migraine, yet the migraines continued. They would be worse if I hadn't had one for a while, but not so bad if they were more regular. They would be preceded by the aura of lights in the eye, and continue for three days as a general rule. During this time I wouldn't be able to read, watch TV, listen to the radio or music, have the curtains open or anything. Just lie in the dark.

A large area in my shoulder became free in the early hours of Boxing Day, and I think this was the cause of the massive migraine that started several hours later. At least it gave me an opportunity to try the fly agaric tincture on a migraine. Since the muscarine in the tincture affects the central nervous system, I was confident that I might get some relief.

I rubbed fly agaric tincture into my head and neck and did experience a great deal of relief from the pain of the headache and stiff neck. I was able to sleep through the worst of it, which is rarely the case for me. The migraine itself (it's a neurological thing, not just a headache) dragged on for nearly a week though. I went for a country walk but had difficulty with hypocapnoea (lack of carbon dioxide), which according to my LLMD is also due to borrelia neurotoxins in my brain stem.

In short I'd definitely recommend trying fly agaric tincture for the pain of migraine, though it didn't seem to lessen the duration any.

I took the image in this post from anthonypeake.com, where I found an interesting discussion about the aura and migraines in general.

External Use of Fly Agaric Tincture on Sciatica, Back Pain etc

Thursday, 5 January 2012

original source: http://flyagarictincture.blogspot.com/2012/01/external-use-of-fly-agaric-tincture-on.html

When I first started investigating the medicinal use of fly agaric tincture, pretty much the only information I could find was on the external application of it to treat sciatica etc, on Henriette's Herbal:

> How to use this then? It's 2-3 drops of tincture on the spine, when sciatica hits. Relief is pretty much instant.
>
> I expect the tincture relaxes the muscles around the spine, where the hurt comes from, and when those muscles are finally allowed to relax they stop clamping bone all over the pinched nerve, which means the nerve can finally relax and no longer scream to the brain that "this hurts, cramp down on this, fast and hard!". And the pain goes away. Bliss.
>
> I learned this from an old Finnish lady years ago - she came up to tell me about it after a lecture. I've told it onwards pretty much every time I remember to, and get very good feedback: "Remember the fly agaric tincture you told us about? Well, we made some in fall, and it helped, and after that the bottle has been in pretty much every house in the village, thanks heaps!". And such.

A friend of mine has been trialling this for as long as I've been on the tincture, seven and a half weeks now. Since she's applying it externally, I was happy there would be no risk for her to give it a go.

Her feedback is extremely positive. She has suffered from backache, diagnosed with scoliosis, for many years, and is in constant pain. The fly agaric tincture has really helped her. One liberal application of the tincture on her back will give her a good six hours of relief at a time.

Spurred on by her success, I've tried applying the tincture onto my painful ear/jaw/neck/shoulder/back/pelvis/rib areas. It's definitely helped with the pain. Furthermore, it's really helping with reclaiming these areas from borrelia colonisation, turning them back from stone (a hard substance, but of course not literally stone) into soft flesh again.

As I understand it, there are muscarinic receptors where the central nervous system meets the muscles, and the muscarine in the fly agaric tincture is acting on these, giving immediate and fairly long-lasting relief. It really is substantially better than ibuprofen gel, deep heat or anything else I've tried. Definitely worth giving it a go if you suffer from sciatica.

hello
came here from ur comment on smart meters with klinghardt. great blog! i want to express gratefulness for ur blog.
i want to hint in the direction of treating chronic lyme. most cheap is the salt and vitamin c treatment, where u intake up to 15 g salt and vitamin c per day. that costs monthly less than $5. but it is to be used for 2y and has severe side effect. but the spirochetes are killed because they are taken the water from. works fine, though i did not try yet.
secondly mms by jim humble shall be tried in my humble opinion (not providing medical advice at all, u know).
what i did try is the use of a combination of detoxing thigns like the chlorella algae combined with the use of antibiotics called Rizols, which happen to be ozonated oils. they work just fine. klinghardt once said, the dosage of gamma and zeta rizols at a dosage of 60 drops daily each moves things. that would cost around $20-45 a month - but it truely works just fine!
as storl suggests teasle works fine, too. some think it just rids the neurotoxins and does not sufficantly treat the lyme. i can just tell that it works for me too.
also there are rife techniques that work fine. rife did blood-electrification. there ought to be working treatments googleable, too.
though we found out about each others through klinghardt, ur suggested to check out the video on hpu from klinghardt, to be found here: http://www.youtube.com/watch?v=9yx-WcBv-oY
feel free to check back in a week or so at my website where i link information about health i find valuable(atm down, next week up again) it is in german language but the video sources are mainly in english language. it is http://www.healthygimmicks.de

I like the idea of connecting. in a world where every information is available for everybody thorugh the world wide web, it is no longer about getting information, it is about connecting the valueable information. thats the main reason i do make a comment like the above. to freely quote klinghardt: u got to detox, detox, detox and on top of that detox as also do alternative antibiotic treatments.
Cheers, man - truely i sense the good idea behind this blog. thank you

Borrelia: infecting people since prehistory

Saturday, 7 January 2012

original source: http://flyagarictincture.blogspot.com/2012/01/borrelia-infecting-people-since.html

A few months ago I surmised that what we call Lyme disease must have been endemic in hunter gatherer communities. With much of their time being spent in and around forests, grasslands and moors, people must have been perpetually exposed to ticks. They must also have been exposed to the diseases that ticks carry, including the borrelia bacteria of Lyme disease.

Indeed, it has recently been shown that Otzi the iceman, the 5300 year old Neolithic mummy found in the Alps, was infected with *Borrelia burgdorferi*. I am not aware of any similar tests having been carried out on bog bodies or other mummies yet, but *Borrelia burgdorferi* DNA has been isolated from 13 of 1,036 mite museum samples in the United States (Persing D, Telford Sr, Rys P, Dodge DE, White TJ, Malawista SE, *et al*. Detection of *Borrelia burgdorferi* DNA in museum specimens of Ixodes dammini ticks. Science 1990;249:1420-3). Mites are also known to carry borrelia bacteria, though most human infestation is thought to come from ticks.

It was the belief that our forebears must have somehow learned to cope with borrelia infestation that led me to search for a readily available natural treatment. I had previously read Wolf Storl's Healing Lyme Disease Naturally, and, though the teasel tincture didn't work for me, it did help to set me in the right direction. Similarly MM Drymon's Disguised as the Devil, or it's much cheaper on Kindle, in which she links the Salem witch trials to Lyme disease. Lyme disease seemed to me to be unavoidable in a society with a close relationship to nature, especially along the edges of woodland.

I was very lucky that the first plant I tried (Amanita muscaria) grows in abundance where I was living at the time, and that it was the growing season (late August to early December) during the time I was looking for a treatment. I cannot imagine life without it now. I have since researched its history and uses, and it does seem that humankind has long enjoyed a close relationship with this plant.

- Amanita muscaria has been posited as the Soma of the Vedic scriptures in Soma: Divine Mushroom of Immortality by R. Gordon Wasson.
- It has also been suggested that it lies behind pretty much every religion on the planet, in John Allegro's The Sacred Mushroom and the Cross.
- It is even implicated widely in the emergence of Santa Claus and our Christmas celebrations.
- I've just finished reading Ploughing the Clouds by Peter Lamborn Wilson, which convincingly searches

Irish myth for encoded references to Amanita muscaria.

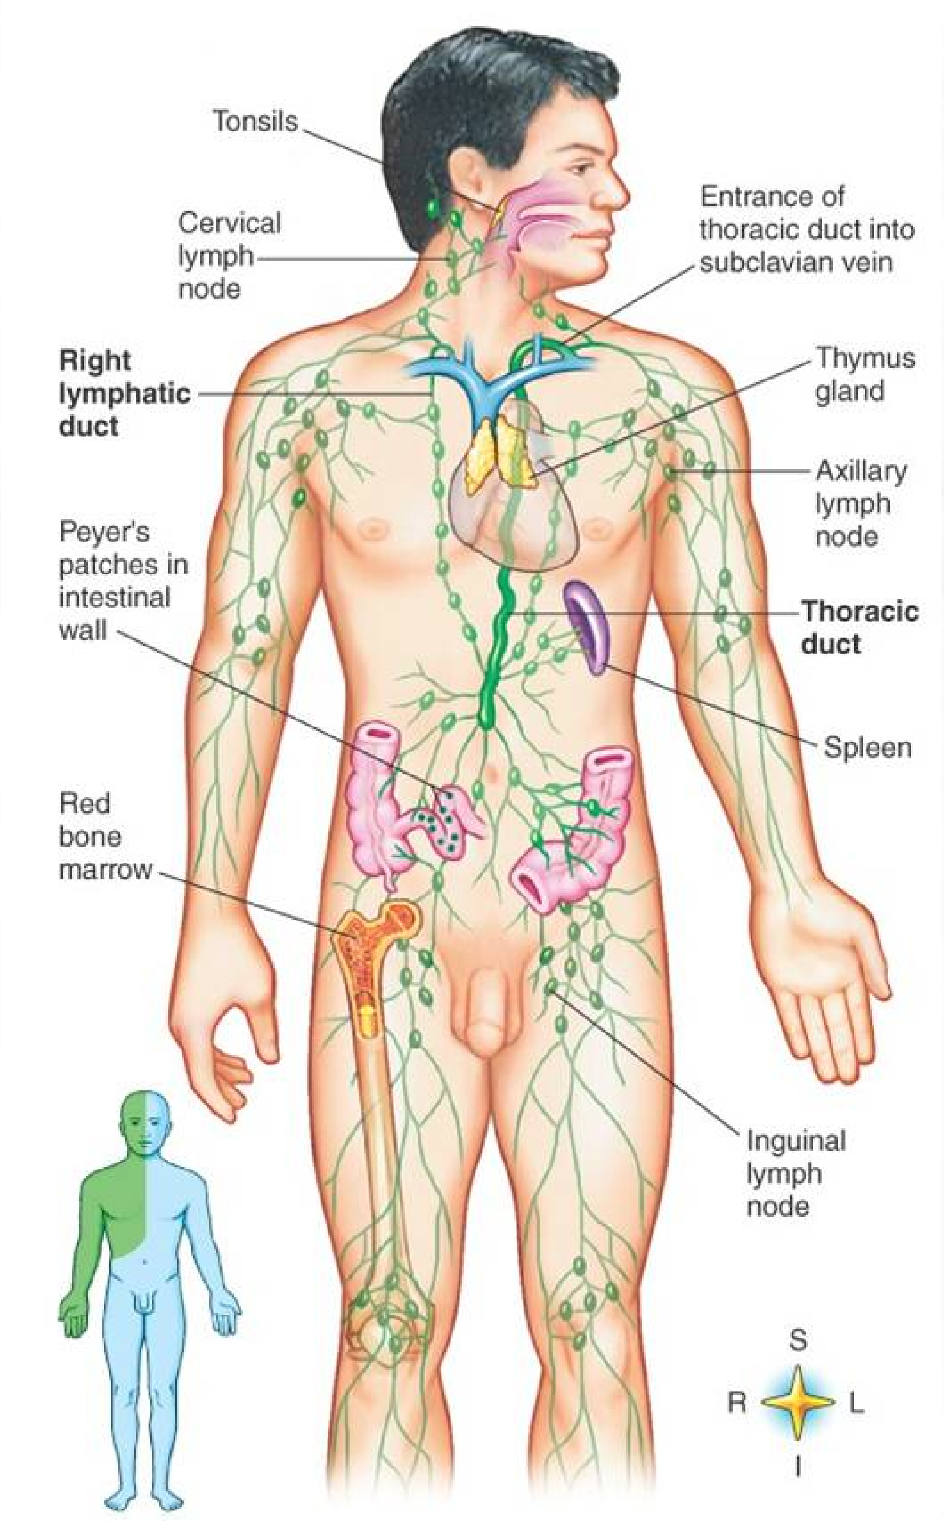
Where people do still live a life similar to that of our prehistoric ancestors, for example the pastoral nomads in northern Sweden, Finland and remote areas of Siberia, the ticks that harbour the disease live in abundance, and infestation with borrelia bacteria is endemic. These are the areas where fly agaric is still traditionally used, and not just for shamanic journeying. It is given in small daily amounts to treat physical fatigue, and poor memory and cognition. The elderly receive it as a matter of course. Is it treating the symptoms of chronic Lyme disease? I do believe so.

Fly Agaric Tincture and the Lymphatic System

Thursday, 19 January 2012

original source: http://flyagarictincture.blogspot.com/2012/01/fly-agaric-tincture-and-lymphatic.html

I have recently found out that my lymphatic system is almost totally blocked in some areas, and has been for many years. This can happen as a result of a bacterial infestation such as Lyme disease. It can also happen as a result of parasitic infestation, which is not uncommon as a co-infection of Lyme disease. People mostly get infected with Lyme disease by ticks, which are characterised as "nature's dirty needle" because they carry so many vile things.



Tonsils
Cervical lymph node
Right lymphatic duct
Peyer's patches in intestinal wall
Red bone marrow
Entrance of thoracic duct into subclavian vein
Thymus gland
Axillary lymph node
Thoracic duct
Spleen
Inguinal lymph node
S
R
L
I

Edit 2/2/12: I don't know if it's physically possible to have such a blocked lymphatic system. It could be crystallised neurotoxins along the muscles near the lymphatic system. Whatever it is, it's breaking down, and my pain is decreasing as it does so.

Before my LLMD (Lyme Literate Medical Doctor) informed me that I was engaging in lymphatic drainage, I had thought that I was massaging calcarised tendons or muscles, as they were so solid. Over the last few weeks, I've been rubbing fly agaric tincture onto the skin above these blocked areas of my lymphatic system. I've also been blasting them with a portable ultrasound machine I have, which has really helped, but here we're concerned about the effects, if any, of the fly agaric tincture.

I have noticed that since applying the fly agaric tincture, the hard and sharp stuff in my lymphatic system has been breaking up much more easily. Apparently the lymphatic system is not far under the skin, so the muscarine in the fly agaric tincture should be able to get to it pretty easily.

I don't pretend to understand the mechanisms of any of this, but I have found that:

> All five muscarinic subtypes have been detected in human lymphocytes; however, receptor subtype expression appears to vary by individual.

(from Muscarinic Receptors By Allison D. Fryer, Arthur Christopoulos, Neil M. Nathanson, Springer 2012. P408)

The fly agaric tincture will not be enough by itself to normalise the lymphatic system. Supporting treatments include Manual Lymphatic Drainage, self massage, exercise and herbal support.

Edit 17/2/12 - Since writing this post I've seen a lymphatic drainage massage specialist, who has confirmed that my lymphatic system is blocked in places. Even after just one session I've felt incredible benefit. I've had a clear head and not suffered the harsher "dementia symptoms" of neuroborreliosis since that first treatment. I had a lot of lymph build-up at the back of my head, which must have been keeping the neurotoxins in the back of my head, where they caused the dementia-like symptoms and problems with my autonomic nervous system, such as hypocapnoea.

Edit 23/1/13 - It now seems likely that the hardness and pain from my lymphatic system may have come about as a result of infestation by a lymphatic nematode or roundworm. These are apparently common even in temperate areas, but aren't normally a problem. When combined with a lack of movement and/or other infection, they can become problematic. I've found ultrasound to be best at breaking down these hard areas, although I always get an increase in neurotoxin symptoms when I do this. Almost constant movement really helps as well, as does keeping warm and hydrated. Cleavers/goose grass/sticky willy is great to help clean out the lymphatics. I'm still not quite done getting rid of it all, but I'm ever closer.

> Hello there - Thanks to your investigations and sharing, I have recently experimented with the Amanita myself. My husband and I both have tick born illnesses, varying degrees of suffering, luckily for us - although my husband has suffered for years with brain fog. Eating a little piece of the mushroom has definitely improved our cognitive abilities, and given us both an "uplift" in terms of mood.
> Very subtle, but life changing.
> I wonder what people are doing while they tincture? I recently did a 1:1 dry mushroom to 100 proof vodka. The vodka was actually diluted to 40% as per Henrietta's advice. I soaked the caps first in distilled H2O and used this water to dilute the vodka. So! It may not be a real 40% dilution - Henrietta is very clear that Amanita is a "liver fryer" - meaning that she advises (strongly) that we label this with "POISON" symbol, and use great care in its administration.
> I mention this to inform, not to frighten.
> Anyone else making their own tincture?
> I have started to give my son the tincture at 6 drops per day. So far no great effect, but I am

taking it very slowly with his treatment - he's on ABX too.
I am grateful to have discovered this wonderful plant, and look forward to learning as much as possible, including a good spot to forage for it come Spring.

Sam Malone *24 January 2012 at 11:24*
Thanks for letting us know mb, and really pleased to hear it's helping you.
I was thinking, as you're buying the dried mushroom, maybe it would make more sense to eat small amounts of the dried mushroom rather than make it into a tincture. I think the dried mushroom tastes really nice, but you can also grind it up into a powder and put it into capsules if you prefer.
In Siberia I understand they air dry the mushrooms, including the stem, and the elderly will then either eat a little bit a few times a day, or make a tea out of the powder.
Sorry I can't find the link for my source for thinking this at the moment.
Best wishes, Sam

Sam Malone *24 January 2012 at 11:49*
Oops forgot to mention, unless you're in the Southern Hemisphere, the fly agaric won't be out until late summer. I've heard of it showing itself in June in freakish conditions, but late August is when they really start to appear.

Three Month Summary

Friday, 17 February 2012

original source: http://flyagarictincture.blogspot.com/2012_02_01_archive.html

Three months ago, I started taking fly agaric to treat my neuroborreliosis, or advanced Lyme disease. Along the way I've found huge relief, and applications beyond treating just neuroborreliosis. So how am I using the fly agaric three months on?

Internal Application of Fly Agaric Tincture

I am still taking drops of the fly agaric tincture under my tongue, to treat the impaired cognition and memory of neuroborreliosis. In the very early days I was eating small pieces of fried and frozen mushroom, which worked just as well, as would eating small pieces of dried mushroom, the way they do it in Siberia. It is also possible to make tea from the dried mushroom, which they also do in Siberia, but I haven't tried this yet.

I've found that there is no specific dose, and that the amount required can vary day to day. The rule of thumb I've gravitated towards is three drops under the tongue roughly every half hour until I feel mentally alert, then as much as is required to keep me that way. It's not as easy as it sounds though, and can be a bit of a rollercoaster while you get used to it. I haven't felt that I was "tripping" at any time though, and haven't had any hallucinations or anything like that.

My memory and cognition are hugely improved, and I've been able to develop mobile phone apps again - namely Ogham (Druid prophecy and tree lore) and Hugin and Munin, a raven based memo program.

External Application of Fly Agaric Tincture

In countries including Latvia, Lithuania, Finland, there is still a tradition of using fly agaric in this way. A few drops are applied externally - rubbed gently into the skin - to relieve topical pain. It seems that this will work for any pain related to the central nervous system, and its effects are complete and immediate and last around 3-4 hours. It really seems to work like magic.

When suffering the agonies that will sometimes hit as a result of my neuroborreliosis, I've applied the fly agaric tincture very liberally, even 10-20ml at a time if the pain is over a wide area. I'm not aware of any dangers using the tincture in this way. Relief is always complete and immediate. It even works for the pain of migraine, but unfortunately doesn't touch the concussion-like hangover of a bad migraine.

External Application to overcome Chronic Fatigue

As part of the process of making the tincture, I run it through coffee filters. This leaves me with coffee filters wet with tincture. On a whim I tried rubbing these over my muscles, covering as much of my body as possible. I almost immediately felt raring to go, and walked without any trouble up a very steep hill nearby, to the castle at the top. I hadn't even been able to make it up the hill before.

As I understand it, the muscarine in the mushroom tincture is enabling the body's electrical signals to reach the muscles, whereas before they couldn't make it over the neurotoxins. I believe that this is probably how the Viking berserkers used to apply the fly agaric mushroom to themselves before battle. It gives noticeably more energy than ingesting the mushroom.

I also apply the tincture externally to any area - usually the back of my knees - that has been over-exerted and is seizing up. Instead of leading to tendinitis and a couple of weeks of enforced rest, the area is generally absolutely fine the next day.

I have also been applying the tincture externally to areas of my lymphatic system that are blocked, sluggish or painful. I can feel and hear the lymph cracking and crunching and breaking down. The improvements there also help counteract the negative effects of the neurotoxins of neuroborreliosis (advanced Lyme disease). I should add, the species of Lyme disease I have are *Borrelia afzelii* and *Borrelia garinii*, the two most common European kinds. I would be interested to hear if anyone is doing anything similar to counteract other species, perhaps most notably *Borrelia burgdorferi*, the most common North American species.

Cauldron of Rebirth

The ancient Celts would take wounded warriors and soak them in a cauldron that restored them so they could return to the battlefield. It has been theorised that the Cauldron of Rebirth contained fly agaric mushrooms with the active ingredient (again probably muscarine rather than muscimol) dissolved in some liquid.

I've been making very diluted cauldrons of rebirth by adding 5-10ml of fly agaric tincture to the bath. It really does take the pain and aches away.

So to summarise this summary, fly agaric has changed my life. It's taken me from being an exhausted cripple with severe dementia-like symptoms to being pretty much a "normal" person again. I can walk for miles, I am reading voraciously, I can string a thought together long enough to write it down, I can engage in conversation, I don't just lie around all day feeling like death any more, and my mood is greatly enhanced.

9 Month Update

Saturday, 29 September 2012

original source: http://flyagarictincture.blogspot.com/2012/09/9-month-update.html

I've now been taking fly agaric mushroom for nine months. I've found that it makes a huge difference to the chronic fatigue, cognitive and memory troubles that result from my neuroborreliosis (chronic Lyme disease).

I initially ate small pieces of the mushroom, moving onto taking the tincture after a couple of weeks. Since the last update, I've gone back to eating small pieces of the mushroom again. These have been dried, since the mushrooms have been out of season.

Since I could find no real information on taking the mushrooms medicinally in this way, I tried different methods, probably focussing too much on the tincture. Luckily I had dried quite a few mushrooms, so was able to compare the different methods.

The effects of eating small pieces of mushroom seem stronger and longer lasting that the tincture, with a slower release. I've still made use of the tincture though, for external application and for a quick cognitive "shot" under the tongue.

Dried fly agaric is used to treat Lyme-like symptoms in sub-arctic areas where Lyme disease is endemic, for example in Pacific Siberia:

> Fly agaric serves the neurological functions of the human body in alternative medicine. The mushroom has been used to treat varying nervous disorders, dementia, dizziness, and Parkinson's disease.
> (from http://www.helium.com/items/2112311-uses-of-fly-agaric-amanita-muscaria-in-alternative-medicine)
>
> Fly agaric is still used in Siberia and Russia especially by elder people to reduce fatigue, to give more strength and to raise the spirit. They mostly make a tea, boiling either dried or fresh cap of mushroom in water for some time. They add honey to the tea and drink it by small portions. It is also considered that Amanita muscaria heal illnesses, connected with aging - sclerosis, insomnia, angiospasm etc. Some people believe that fly agaric has antitumor and immunostimulating

> properties.
> (from http://www.helium.com/items/1732849-can-i-use-fly-agaric-for-healing)

Fly agaric is far and away the best treatment I have tried since finding out that I have chronic Lyme disease (neuroborreliosis). There are probably many facets to its action, but the most important one is the muscarine in the mushroom enabling nervous system signals to jump over the Lyme neurotoxins that clog up the neuroreceptors.

The amount of mushroom needed does vary, due to the differing amounts in individual mushrooms, and the current level of neurotoxin load. It is hard to estimate the size of a daily piece, as much depends on how much it has been dried, and how much of its water content it has lost. Starting with a piece the size of the top little finger joint is perhaps the best way to go. If nothing has happened in half an hour, another piece can be taken.

At no point have I felt even remotely "trippy" - only "normal". It is like awakening from an enchantment. Suddenly you can think again, you can move, you can remember. There's no need to lie around trying to summon the strength to do the slightest little thing. It's done almost before you've started to think about doing it. I have had regular blood tests to check liver function, and everything has been totally fine.

I feel the mushroom has restored enough of my cognition and memory for me to live, though I am not (quite) yet working again. It has also given me the energy to have a good country walk of a few miles every day. This exercise has been of immeasurable benefit to my lymphatic system and my general well-being, including happiness levels. Especially as for three and a half years I could barely walk, and thought I would be stuck in a wheelchair for life. This was before I found out that it was Lyme disease behind it all.

If you would like to discuss any of this further, please do not hesitate to contact me. I may not update this blog again, as I'm going to concentrate on Fighting Lyme Disease, showing how you can make herbal treatments to treat and beat the Lyme.

Here are some Russian fly agaric medicinal recipes that I've found by searching via Google for "Мухомор красный" - literally "red fly killer" - which is what fly agaric is called there. I haven't tried these, but thought I'd publish them here so that people have access to them. Thanks to Google Translate for the translation.

Treatment of red fly agaric
Offer readers a unique recipe means that our ancestors were treated. They were treated much the drug. Intervertebral hernia, diseases of the joints, cracked heels, shipitsy (bones) in the legs, ulcers, various skin diseases. This is a brown thick ointment softens easily at 37 degrees. In the ointment is the dried powder of Amanita muscaria. For the preparation of medicines are needed only red mushroom.

To dry amanita at less than 60 degrees. Need rye flour that does not contain stabilizers, disintegrants. Better rye by grind in a coffee grinder. Pine sap resin can replace any tree. Resin - a valuable medicinal ointment component that delivers medication to the patient body. Along with a natural preservative for the mushroom body fat. The shelf life of the oil - a few years.

In a water bath to keep the enamel mug 50g unsalted visceral fat. As the fat melts, add the dried red mushroom powder 30 grams, 10 grams of rye flour, pine sap 10 grams. Thoroughly mix all until smooth. Keep a medicine in a glass container in the refrigerator.

Intervertebral hernia, painful joints before applying means warm light massage camphor oil. Back (joint) after rubbing ointment wrap woolen cloth to keep warm through the night. Camphorated oil in the other cases is not required. Cracks, minor wounds, insect bites, herpes grease composition just before full recovery.

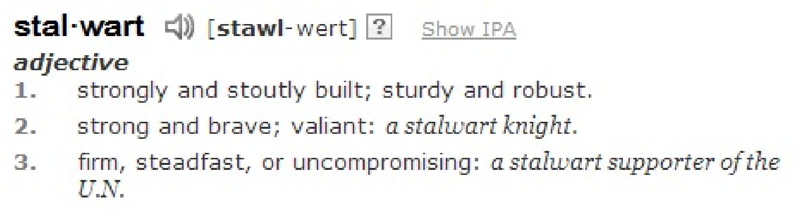
Ulcers, large wounds, fistulas are treated differently. Wound before treatment should be washed with a disinfectant solution (potassium permanganate, furatsilin, galangal broth or tsetrarii). Next, using the end of a lime glow sticks dry. Ignite this dry lime-stick (you can replace the currant), blow out the flame, the surface of the wound led to the end of the glow for 3-5 minutes at a distance of 1-2 cm. Do not worry: the burn will not be felt coolness.

Emergency procedure promotes tissue regeneration of the skin. Wound will heal much faster. Then apply ointment to a clean linen cloth the size you want a thin layer applied to the wound. Secure the elastic mesh or bandage. Ligation done daily until recovery.

Stalwart: forgotten folkname for fly agaric

Wednesday, 23 January 2013

original source: http://flyagarictincture.blogspot.com/2013/01/stalwart-forgotten-folkname-for-fly.html



stal·wart [stawl-wert] ? Show IPA

adjective

1. strongly and stoutly built; sturdy and robust.
2. strong and brave; valiant: *a stalwart knight.*
3. firm, steadfast, or uncompromising: *a stalwart supporter of the U.N.*

The fly agaric is such an iconic mushroom, instantly recognisable, with a long relationship with the human race. Yet we have no English folkname for it. I propose that stalwart is a forgotten folkname for fly agaric.

The word "stalwart" is of largely unknown etymology. The Online Etymology Dictionary has:

> **stalwart** (adj.)
> late 14c., Scottish variant of Old English stælwierðe "good, serviceable," probably a contracted compound of staðol "foundation, support" (from P.Gmc. *stathlaz, from PIE root *sta- "to stand, set down, make or be firm;" see stet) + wierðe "good, excellent, worthy" (see worth). Another theory traces the first element of stælwierðe to Old English stæl "place," from P.Gmc. *stælaz.

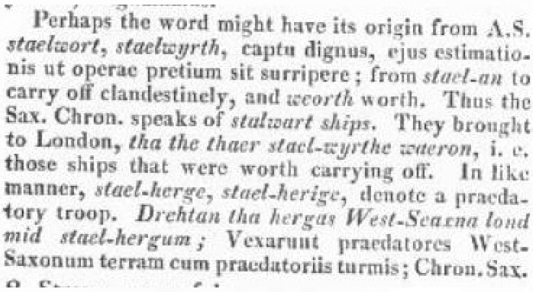
It is clearly made up of two different parts, "stal" and "wart".

- "Wart" could easily be a corruption of "wort", the old English word for "plant" - seen, for example, in St John's wort. Stalwart was often spelt "stalwort" historically.
- "Stal" could easily be a shortening of the old Germanic word for mushroom, surviving into Dutch, for example, as "paddenstoel". Although this sounds more like toadstool than mushroom, it is a generic word for fungi with a hat and a stem. This word actually has the same etymology as the stal above - meaning a foundation, support. It is also the origin of the word "steel".

The word "stalwart" is usually used to describe a warrior or a hero, someone who stands strong. This perhaps suggests a connection with ancient fighting forces. It is widely believed that Viking berserkers - and perhaps other warriors, notably Celts - made use of the fly agaric in battle. Therefore a fighter would be considered "stalwart" because they had partaken of the stal wort, the mushroom plant.

Having performed a little archaeological experimentation regarding this, I would posit that the warriors would cover their skin in fly agaric juice, and probably take a bite also. Strength and stamina are increased, and fear dissipates. There is a feeling of immortality. All these are qualities likely to make a warrior stand firm and fight for glory in battle.

Thus the berserker is shielded by the mushroom, which he also takes a bite from. Perhaps this is what the Isle of Lewis chesspiece berserker here is telling us as he bites his shield.



Perhaps the word might have its origin from A.S. *staelwort, staelwyrth*, captu dignus, ejus estimationis ut operae pretium sit surripere; from *stael-an* to carry off clandestinely, and *weorth* worth. Thus the Sax. Chron. speaks of *stalwart ships*. They brought to London, *tha the thaer stael-wyrthe waeron*, i. e. those ships that were worth carrying off. In like manner, *stael-herge, stael-herige*, denote a praedatory troop. *Drehtan tha hergas West-Seaxna lond mid stael-hergum*; Vexarunt praedatores West-Saxonum terram cum praedatoriis turmis; Chron. Sax.

Pictorial extract from An Etymological Dictionary of the Scottish Language: Volume 2 By John Jamieson, Edinburgh University Press 1808.

Within the Saxon Chronicles there is the word "staelwort", with a meaning of "to carry away clandestinely". It is likely that any fly agaric mushroom sect would - like those written about by Wasson and Allegro - have secret means of obtaining the mushrooms, carrying them away in a process known only to initiates, and probably subject to much ritual.

Indeed, Wiktionary has "stæl" as meaning "theft", akin to the Old English "stalu", all from the same Indo-Germanic root. This is suggestive of another very interesting possibility, that "stalwart" could be "the stolen plant".

Part of the mythology of the Vedic soma is that the plant be stolen from its guardians. Theodora, from A. A. Macdonell, Vedic Mythology (Strassburg, 1897), explains:

> The first soma is supposed to have been stolen from its guardian demon by an eagle, this soma-bringing eagle of Indra being comparable with the nectar-bringing eagle of Zeus, and with the eagle which, as a metamorphosis of Odin, carried off the mead.

- mushroom plant
- strength plant
- foundation/support plant
- secretly-carried-away plant
- the stolen plant

and could even provide another clue that perhaps fly agaric does equate with the Soma of the Rig Veda, and is indicative of an ancient entheogenic practice surviving in Indo-European Britain and Ireland. Such is investigated in PL Wilson's excellent Ploughing the Clouds: The Search for Irish soma.

It is, of course, possible that more than one of these meanings could also apply, in a play on words, for example, "the stolen plant that makes strong", even providing "foundation" for a whole culture.

Letters from Russians who have used fly agaric medicinally

original source: http://flyagarictincture.blogspot.com/2013/02/letters-from-russians-who-have-used-fly.html

Here are some letters from Russians who have used fly agaric medicinally. I found these at shamanika.biz. I do hope they are happy with them being reproduced here. Copyright is attributable to (C) Makeyenko TV Physician. Translation from Russian by Google Translate. The whole of this article is from that webpage. I have written none of the following ...

Lung Cancer

(Letter of Anapa on K st Tatyana Alexandrovna). In 1969, my father (I was living in the city of Tyumen) ill - lung cancer. From the operation, he refused - he was immediately discharged from Oncology Center. His condition was terrible. They waited for the worst ... But at the hospital someone advised to drink mushroom hails vodka. Start was terrible. But he decided, at first spoonful 1.5 months, then a shot of the infusion, and then could drink a bottle a day of the liquid (the good liked to drink.) Its age was then 60 years old. And the state just two months later began to improve. Went phlegm with cough, with black - coal dust (he also worked on a locomotive engineer), sputum was intense. That's it then spent 13 years with breaks drank mushroom. Even little by little moonlighting guard, went to the forest for one mushroom. Then he gave them in the winter, who addressed. His father died with a diagnosis of pulmonary hemorrhage, ie, where there was a focus of the tumor - this place is just physically worn out.

Lung Cancer. Stroke

(Letter from the city of Yaroslavl on T-tion Nina Vasilievna). My husband literally not even a year old, he died of lung cancer. But I suggested and even gave ready hails mushroom in the primary moonshine, because now the pure alcohol can not get anywhere else. Describe how it healed. Gave the scheme from the 1st drop and brought to 20 drops 3 times a day for 15 - 20 minutes before a meal, and went back to 19 drops, then 18 and so on and brought to 7 drops. But he did not know that drinking mushroom. I once said to him: Serge, Let's have a fly agaric. A: what about you? Are you crazy? Decided to poison me? He did not know it was drinking it, because I'm in a thermos overnight insisted in hot water rose, the color was brown, and add 1 tablespoon of honey. Temperature husband reached even 40 degrees. Injections: analgina, diphenhydramine, but-silos 2 times and it was 3 times, but to no avail, and she started to drink Amanita - he recovered a bit, ate everything, began to leave himself out, he tucked in bed with him. A headache cough and he went to a therapist, and came to the reception, the doctor was surprised that he got up and danced in front of her dance. The doctor did not believe that he is on his feet. The pressure was high, and there is normal.

And so while drinking mushroom - was healthy. But as I said to him, and you do have drink, quarreled and did not drink. Decided to take a break, but you can see the cancer was extensive. A daughter of our smart, graduated from the Institute on excellent, scolded him that you mom treats, wants you to have lived, and you do not drink mushroom. And he agreed to drink. And because it was a big break, began to give one a bit, but apparently it was not enough. You had told me something like a 8 or 9-drops and no break you and your husband have been through. So I regret it all. He was my benefactor, and morally supported me. But alas, no one has suggested a break, as well as because of drops to give him.

Husband died, I go to the grave and weep, but that has not stopped. Went into the forest, gathered muscaria, got a little moonshine and double stage set for 1 month. I myself drink it now. Stomach ache, was not hurt. And when one went to the grave and met a woman and she told me that her relatives a woman 40 years hit paralysis. Her husband got this one year hails mushroom and watered for about a year and now she works as a cleaner and even dance. All she departed, and her husband said to his feet, and all what happened.

Stomach cancer

(Letter of Solikamsk from K-th Valentina). I had a case. My husband had surgery perforated ulcer. Managed to sew. Lived for 8 years. What was spring, autumn relapses. Decided to go to a resort, was examined and passed. Admitted to hospital, the operation did not do. Than treated - injections. But I was wearing a hospital mushroom. Tincture made two weeks in a dark place for 3 cap mushroom to 0.5 liters of vodka. So hats were not blooming, red. He drank in the morning on an empty stomach half a spoon and a mummy with the head under the tongue to dissolve the match and finally butter. FGS was autumn and the doctor said everything was fine. Already passed 7 years. I think he helped mushroom. A recognized cancer. Stomach cancer.

Rheumatism

(Letter of Saransk from A-ing Inessy Vasil'yevna). I was operated on for cancer of the stomach, removed 1/2 of stomach and I made medicine from mushroom to grandmother's recipe and here for 3 years I drink this medicine with 1 drop of 25 and until the 1st 50 days, then break for three weeks, and again. My mother was a terrible rheumatism, she began to drink with me, and now walking without crutches and sticks and legs swell.

Uterine cancer, throat cancer

(Letter from the Voronezh region from K-hand Raisa Grigorevny). I had no ill. His whole life was in the hospital two times: birth, 2 daughters from me. Ill eight years ago. Profuse bleeding, thick pieces. The district hospital said: "Climax". And discharged. I lie at home. I feel sick. I can not get up. Blood clots. Husband drove the ambulance to the regional oncology. Diagnosed with adenocarcinoma. Difficult surgery - deleted all a woman. Final diagnosis: chorionepithelioma. ESR - 68. From chemotherapy refused flatly. The tablets did not drink, all ejected. Lay on the table under the irradiation with a prayer: "Save me, O Lord." Immediately got up and into the shower, all washed away. A secret from the doctors saw mushroom (tincture). After irradiation greatly hurt the liver, stomach upset: neither eat - diarrhea, did not hold urine. When the pain was impossible to sleep, then saw a double dose of mushroom. Soothing.

For 1 year, I drank 3 liter jar mushroom infusion. I forgot where the liver. Normalized stomach, urinary bladder. Without re-examination I was given life the 2nd level of disability. But with God's help, I work as a teacher at a school in a full load. Of course, very tired. God gives me patience, contentment and joy in the soul. I do not have depression, resentment, bitterness, resentment. In the bustle of everyday life, I always turn to God. Churches have not. I read the Bible - a wonderful source of spiritual and pray. Understood the main thing: we are all under God. I'm worthless instrument of God.

Another case of healing mushroom. 3 years ago after her husband became ill, my friend. Cancer. Initially uterus removed, and then the right breast. Cancer in stage 4. Earth collapsed! Her sons asked, "Help!" Doctors were warned of deaths. I went to her in the hospital and begged him not to do chemotherapy pill or drink, or fly agaric mushroom will not help. Chemistry did not, said that all going to die. Saw mushroom after eating (to food - could not). Combined Saw distilled kerosene. Every day, I visited her and inspired not to lose heart. Recovered. Now works in its place - the chief accountant of the farm. Rejoice! Kind! Do not allow discouragement in his soul. He lives with God! Praying. In oncology, I noticed that died, those who went into the disease, limp, he was afraid of death. A person has to control himself. This is very important!

How did I know about the fly agaric? Nowhere read, are not met. My husband's brother (Yoshkar-Ola lives) grazed cattle. He noticed that the sick cow and mushroom grab greedily munching. Looking, run to where the red mushroom. And they get better. One day he was found shot in the throat. Grew. Covered passage. Doctors said, "Cut! Cancer." He did not return. Scored mushroom cap, was there, so it was fun to die, washed down with vodka. There was all black as tar, all cleared, lump disappeared. It took 40 years. Now he is 80. Lives. Amanita drink in their scheme. He cured the daughter-in-law, which removed both breasts. It works too, though afraid of the sun.

Dear Tamara, your brochure I need not to treat (we're healthy), but in order to compare with the experience, a way of making drugs, self-control, system usage. It's medicine - poison. One time I was poisoned, as tincture of mushroom was not sustained over time. His stomach was washed with water and baking soda in large quantities.

Stomach polyps

(Letter from the Tyumen region of M Victor Mikhailovich). I want to tell you how I was treated mushroom. Prompted me one recipe Grandma (now deceased). My wife was a cancer patient. That's grandmother and persuaded me to insist mushroom. She gave me a dry mushroom, which I insisted on vodka 0.5 liters of 18 days in a cool dark place. Wife then refused to drink this infusion. And I had eight polyps in the stomach. Then I decided to take myself this infusion. Peel, as taught - 1 nightingales spoon 3 times a day for half an hour before meals. Drank all the brandy, well, as if no change is noticed, and when Moscow offered to do the surgery - to remove polyps, when the survey revealed that they have not. Asked what was treated. Other drugs, except mushroom, do not drink. Treated differently, some believed, some laughed. But I do know that it is from mushroom. And the result is there.

Disease of the breast

(Letter from Krasnodar from B-k_Nadezhdy Feodorovna). Amanita muscaria, I am treated eighth year and it helped me a lot. 9 years ago I had an operation, "Fibroadenoma right breast." But in spite of the operation, I have continued chest ache, a rough, pink, bad joint. And the worst thing that was for me, it became a bother and left breast. I had a record, after 2 - 3 months was at the doctor's office. The pain was such that I feared so God forbid someone touched me. Suggested a second surgery, I refused, since mammograms have become the defining features of diffuse fibrous mastopathy.

2 years after the operation, I began to drink brandy mushroom, I always send it to my sister from Sverdlovsk. Saw her almost eight years now ended. Pain did not bother me a year three - four, but I kept taking it from 15 to 45 drops, adding one drop every day. The last three years have always drank a tablespoon for a month, then a month break, and so on for the last 3 - 4 years, I can no longer even lie on your stomach, but not abuse, basically try to sleep on your side or back . You know, Tamara, over the years I have something to do with this tincture feel safe, even if it is just in the fridge and I did not drink for a while, I feel more confident and relaxed that I have it. Now infusion over, I feel like I'm losing confidence, some confusion.

Stomach cancer 2

(Letter from the Bryansk region of I-to AM). I will be very grateful if you send me a brochure entitled "Treatment of fly agarics." I am not sick with cancer, and an ad in the newspaper would not have paid any attention if he did not know the case in the neighboring area. Wife wanted to poison her husband mushroom. He was discharged from the hospital to live out his days at home. He had stomach cancer. Severely tortured and tormented her as drinking began shamelessly. So, fry toadstools, gave them to the table as the mushrooms with a bottle of vodka. Recovered and lived for many years after this event. And even more treats from all diseases infusion of toadstools.

Longevity

(Letter of Boksitogorsk from A-va VT). If the truth can send a brochure entitled "Treatment of fly agarics", I'll wait. I kid read "Aliket go to the mountains" - so there is a moment that shamans used dried mushroom stem. Then my neighbor, an old man insisted on amanita brew and drank and lived, although the doctors were surprised that he did not die for a long time. Earlier in his youth, I somehow did not pay attention to it. But now I'm 59 years old and it's time and I'm interested in this tincture. But how to prepare it - that's the question.

Comment

Information that the fly agaric tincture drink to prolong life, I have many. Also this beautiful property it often read in the literature. In addition, the mushroom causes a rush of energy, stimulates physical and mental endurance, has the property to quickly restore lost power. But! used for continuous use as a stimulant mushroom can not, because it is a poison and narcotic. Only courses and in small doses! Mushroom use as drugs started in Russia about 10,000 years ago. Alkaloids contained in Amanita cause poisoning, hallucinations, and addictive. Another effect is that are near objects appear either very large (makropsiya) or very small (mikropsiya). Possible movements and convulsions. Episodes of intense excitement turns to moments of deep depression. Amanita muscaria, in contrast to other hallucinogens, causes an abnormally severe physical mobility. Indigenous peoples of Siberia - the Chukchi, Koryak, Kamchadals and others - are widely used amanita in several cases: to communicate with the supernatural in order to predict the future, to determine the cause of the disease, as well as just for fun during festivals (such as weddings) when they treated guests. And, of course, is widely used to enhance the abilities of mushroom shaman.

Questions - Answers

How to prepare and take the medicine of toadstools?
The answer is: preparation methods and regimens - a few dozen. (There is even such a seemingly frivolous as infused with male urine amanita. Well, this is unusual cooked mixture (with fly agarics on urine of men) is a natural drug and is used for severe pain in cancer patients).

Which one to choose - solves your fitoterapevt or healer, who you're going through treatment, and who is responsible for the drug and for you. Self poisonous herbs and mushrooms to engage strongly advise. But if you can not be treated by a specialist (which is much more effective than self-medication), use 50% tincture of vodka under the scheme: start with 1 drop 3 times a day for half an hour before meals, daily increasing the dose of each meal and 1 drop and work up to 20 drops 3 times a day. Then drops down, reducing the daily dose of 1 drop at each visit. Break - 1 week. Conduct at least 3 courses in a row.

Mushroom tincture drink better with 0.5 glasses of water infusion of birch fungus fungus or drop it 1 tablespoon diluted Befungin - pharmaceutical drugs fungus.

To prepare the tincture used only hats. Cut them into small pieces, weighed, placed in a jar, add an equal amount by weight of vodka and infuse at room temperature in the dark for 1 month.

The second method. Hats chop the brim lay in a jar, close the nylon cover, tie a cloth and buried in the ground to a depth of 1 meter for 1 month. Then drain the resulting juice and add some to it an equal amount of vodka. Store at room temperature tincture in a dark place out of reach of children. Shelf life - 1 year. And once again, remember that it is a poison.

50% tincture is used only if the patient takes of poisonous herbs only one mushroom. If you use an integrated, enhanced treatment (several potent herbs and ointments), the concentration, dose and regimen of others. When non-cancer diseases, use a weaker tincture - 10%.

In general, well said, responding to a similar question, healer of Moscow Vladimir Mironov, successfully using mushroom and brandy fly agaric ointment for the treatment of various diseases, including cancer, "I specifically do not include a recipe here fly agaric tinctures. It requires accurate compliance dosage. And then tell me how it is prepared, - in the woods any mushroom will not. Yet mushroom - mushroom special. Hence drink liquor only under close supervision."

Tell us how to prepare a tincture of hemlock.
To prepare the tincture using fresh flowers and green unripe seeds, in these parts of the plant contains many alkaloids. Fresh flowers are crushed, weighed, placed in a jar and pour vodka quality by weight in the ratio of 1:10, for example, 100 g of flowers we have to take one liter of vodka. Keep the vodka was no additives, particularly acidic - like citric acid, whey - for then alkaloids bind and precipitate, liqueur turns cloudy. Infuse 3 weeks at room temperature, and always in the dark. After 3 weeks, strain. Next. After 2 - 3 weeks after harvesting flowers (depending on weather conditions) Collect green unripe seeds of hemlock. Of them the same way, prepare 10% tincture 3 weeks strain. Then mix equal parts both tinctures: from seeds and flowers, shake well. Tincture of hemlock is ready for use. You can store it at room temperature, always in the dark and always out of reach of children. Shelf life - 1 year.

What is the stronger of the herbs - hemlock, aconite, or mushroom? Where should I start treatment?
By the force of the antitumor effect of these herbs are equal. Depending on individual sensitivity of some patients are better at Hemlock, others to Akon, third on the mushroom. Of cancer patients do not have time for the selection, so I always assign a comprehensive, enhanced treatment: all three infusions made in the same day at different times. Besides infusions necessarily give their patients herbal ointment - lubricate the affected area and the nearby lymph nodes. In the ointment are hemlock, mushroom, aconite, milestones, henbane, and some other herbs and pharmaceutical ingredients to improve skin permeability. The main property of the ointment - the local anti-tumor effects. In addition, it has analgesic and good wound-healing effect (when a cancerous ulcer, for example, splitting the running breast cancer).

I was approached by a young man from Polotsk - cancer of the penis. In Minsk, underwent surgery. Does not heal within a year post-operative wound. Tried all assigned ointment treated laser - without effect. Gave her ointment. Ringing. Happy, all is well. Regret only one thing - he had heard from patients about me good reviews, but somehow I did not believe in the grass. Year wondering whether to apply to me. And helped salve for several weeks. In benign tumors, treatment, I usually start with hemlock. In most cases, this is enough. When failure of hemlock select another tool.

Fly Agaric and Radiation Burns

Saturday, 23 February 2013

original source: http://flyagarictincture.blogspot.com/2013/02/fly-agaric-and-radiation-burns.html

I was very surprised to find that fly agaric is used externally as a remedy for radiation burns in Russia (eg "an effective tool in radiation injuries of the skin"). I was even more surprised when it turned out I had radiation burns myself, and was able to use the fly agaric to treat them.

For the last two years, since I got my first smartphone, my thumbs and index fingers developed very deep splits in them. It seemed that the splits went all the way through the skin. They were very sore, and often very itchy, unbearably so. They had yellowy orange scabs surrounded by red soreness.

A month ago, I suddenly realised that the splits, redness and soreness were exactly where my smartphone touched my hands. I thought perhaps it could be radiation burns, and stopped using the mobile phone. Instead, I started using a netbook much more. The splits largely healed up. But the skin on my index finger, where it touches the mousepad, became very hard and sore.

I bought an electromagnetic radiation meter to see how much radiation - if any - these devices were giving off. I was shocked to see how much EMR (electromagnetic radiation) they were giving out, and continuously, rather than in pulses. Since then I've stayed off the netbook as well as the smartphone, and am only on the computer for short periods of time, using an external keyboard.

My hands are still scarred, but they haven't split again, for the first time in two years. I am satisfied that the splits and soreness were EMR burns. They looked just like the least severe images if you type "radiation burns" into Google images.

Treating Radiation Burns with Fly Agaric

I can't remember what I treated the burns with for the first year. For the second year though, once I'd discovered fly agaric, I treated them with fly agaric tincture, as I'd found it to be great at healing cooking burns and any little cuts, cat scratches etc. The splits would heal up, and become less sore, but they would always return before long, usually just a few days.

Once I realised that they were radiation burns, I tried a fly agaric compress. This was basically just a piece of mushroom soaked in vodka and taped onto the thumb and finger of one hand. This probably isn't the correct way to make a fly agaric compress. It made the skin around the burn look as if it had been in the bath for a week. It didn't feel as if this was the way to treat it, so I went back to just applying the tincture every hour or two, and leaving the wounds open to the air.

Sure enough, when applying the fly agaric tincture onto the radiation burns, they healed up quite quickly, within a few days, especially once I stopped using the netbook as well. They're still scarred, but at least they aren't split or scabbed anymore.

I found that the alcohol in the tincture dried the skin on my hands out. At this point, it would be great to have a fly agaric lotion to apply. I have experimented with coconut oil and powdered fly agaric, but it hasn't really worked out. I hope to find a way to make a fly agaric lotion, or at least manage to find somewhere I can buy the Russian fly agaric lotions.

Of course, sunburn is also a form of radiation burn, and fly agaric may be helpful in treating this as well.

Regrettably, all the photographs I took of my thumbs and fingers at various stages in the healing process are blurred and unusable.

Fly Agaric Protects Against Aging and Neurogenerative Disease

Monday, 21 July 2014

original source: http://flyagarictincture.blogspot.com/2014/07/fly-agaric-protects-against-aging-and.html

Research shows that stimulating muscarinic receptors protects the brain and central nervous system against aging and neurodegenerative disease.

> These results demonstrate that stimulation of muscarinic receptors provides substantial protection from DNA damage, oxidative stress, and mitochondrial impairment, insults that may be encountered by neurons in development, aging, or neurodegenerative diseases. These findings suggest that neurotransmitter-induced signaling bolsters survival mechanisms, and inadequate neurotransmission may exacerbate neuronal loss.

Fly agaric mushrooms contain tiny amounts of muscarine, which acts as a stimulant to muscarinic receptors. So does eating a small daily piece of fly agaric mushroom protect against neurodegeneration? The elders of some native Siberian peoples eat a little fly agaric every day. They say that it gives them energy and helps them to think and remember things. It would seem that it is likely also protecting their brains and nervous systems against neurodegeneration related to aging.

Chemicals and Compounds of the Fly Agaric

The different chemicals and compounds found within the fly agaric mushroom. The quantities of these can vary wildly from mushroom to mushroom, and even within one mushroom. Some of the chemicals can cancel each other out (for example atropine and muscarine), but with slightly differing amounts, there can be very different effects.

Muscimol

Muscimol stimulates GABA receptors. GABA is found throughout the plant and animal kingdom, and may represent a ubiquitous biological signalling molecule between animals, bacteria, fungi and plants (http://sydney.edu.au/medicine/pharmacology/adrien-albert/images/pdfs/RefsPDFs/390.pdf).

Muscimol is a crystalline solid that melts at 175C. It has neurologic activity and is a potent depressant of the central nervous system. The adverse effects of ingestion include sleep, hallucination, distorted perceptions and vomiting. (A Comprehensive Guide to the Hazardous Properties of Chemical Substances By Pradyot Patnaik 2007)

Ibotenic Acid

Ibotenic acid can be used in a similar way to monosodium glutamate, to improve the flavour of foods.

> Tricholomic acid and ibotenic acid can prevent deterioration of food and separation of Water therefrom, and keep the freshness and vivid appearance thereof; for example, when either of them is added to food paste, it improves color and increases viscosity and elasticity; when added to sake (rice wine), it prevents deterioration, when added to miso (bean paste) or soy sauce, it increases stability; and when added to milk or its processed matter, it lowers curd tension and promotes digestion.

The insecticidal properties of fly agaric are a result of ibotenic acid (Takemoto et al, 1964). Experiments have shown that the insecticidal activity of tricholomic acid is superior to that of ibotenic acid.

Muscazone

Muscazone is a crystalline solid amino acid that decomposes above 190C. It's sparingly soluble in water. The toxic symptoms from high doses are similar to those from ibotenic acid. (A Comprehensive Guide to the Hazardous Properties of Chemical Substances By Pradyot Patnaik 2007)

R-4-hydroxy-pyrrolidone

This chemical frame is common in some micromycetes; they generally exhibit a potent biological activity against bacteria and other fungi (e.g. aureothrycin, equisetin). This additional compound, gives information on the biogenesis of ibotenic acid, muscimol, and muscazone.

Tricholomic Acid

Tricholomic acid can be used in a similar way to monosodium glutamate, to improve the flavour of foods.

> tricholomic acid and ibotenic acid can prevent deterioration of food and separation of Water therefrom, and keep the freshness and vivid appearance thereof; for example, when either of

them is added to food paste, it improves color and increases viscosity and elasticity; when added to sake (rice wine), it prevents deterioration, when added to miso (bean paste) or soy sauce, it increases stability; and when added to milk or its processed matter, it lowers curd tension and promotes digestion.

Muscarine

Muscarine is a non-selective agonist of the muscarinic acetylcholine receptor. It crosses the Blood Brain Barrier. Muscarine mimics the function of the natural neurotransmitter acetylcholine in the muscarinic part of the cholinergic nervous system. Muscarine is not metabolised by acetylcholinesterase.

Bufotenin

(5-HO-DMT, *N,N*-dimethylserotonin), is a tryptamine related to the neurotransmitter serotonin. It is an alkaloid found in the skin of some species of toads; in mushrooms, higher plants, and mammals.[1] The name bufotenin originates from the Bufo genus of toads, which includes several species of psychoactive toads, most notably *Incilius alvarius*, that secrete bufotoxins from their parotoid glands.[2] Bufotenin is similar in chemical structure to the psychedelics psilocin (4-HO-DMT), 5-MeO-DMT, and DMT, chemicals which also occur in some of the same fungus, plant, and animal species as bufotenin. The psychoactivity of bufotenin has been disputed, though recent studies suggest it is similar in nature to 5-MeO-DMT. (from Wikipedia)

Choline

Choline is the precursor molecule for the neurotransmitter acetylcholine.

Acetylcholine

Acetylcholine is an organic molecule that acts as a neurotransmitter in many organisms, including humans.

Betaine

A betaine is a neutral chemical compound with a positively charged cationic functional group. It is also a methyl donor of increasingly recognised significance in biology.

Atropene

Is an antidote to muscarine.

Muscaridin

Hercynin

May act as a precursor of trimethylamine (Nielsen, J. Trimethylammonium compounds in Tilletia spp., *Canadian Journal of Botany*, 1963, 41(3) p. 335-339.). Trimethylamine is used in the synthesis of choline, itself a precursor of acetylcholine.

Uracil

One of the four nucleobases in the nucleic acid of RNA. In DNA, uracil is methylated and becomes thymine.

Xanthine

A mild stimulant and broncho-dilator. Increases alertness in the central nervous system. Stimulates the respiratory centre and is used in the treatment of asthma and infantile apnoea.

Hypoxanthine

The *Pheretima aspergillum* worm, used in Chinese medicine preparations, contains hypoxanthine. (The Pharmacology of Chinese Herbs, Second Edition By Kee C. Huang)

Adenosine

Very important in human energetic processes, as ADP, ATP and cAMP. It is also an important neurotransmitter in falling asleep. Adenosine receptors are key to opening the Blood Brain Barrier (BBB). Adenosine is also believed to have anti-inflammatory properties.

Bug Agaric in Herbal Simples for Modern Uses of Cure (1897)

The following is from Herbal Simples for Modern Uses of Cure (1897) by William Thomas Fernie:

The pileus of the Fly Agaric is broad, convex, and of a rich orange scarlet [369] colour, with a striate margin and white gills. It gets its name, as also that of Flybane, from being used in milk to kill flies; and it is called Bug Agaric from having been formerly employed to smear over bedsteads so as to destroy bugs.

Bois un peu frais. — Été, automne.
Fausse Oronge. — Amanita muscaria.
— Très vénéneux —

It inhabits dry places, especially birchwoods, and pinewoods, having a bright red upper surface studded with brown warts; and when taken as a poisonous agent it causes intoxication, delirium, and death through narcotism. It is more common in Scotland than in England. This Mushroom is highly poisonous, and therefore the remedial preparations are only to be given in a diluted form.

For medicinal purposes a tincture is made (H.) from the fresh fungus: and a trituration of the dried fungus powdered and mixed with inert sugar of milk also powdered. These preparations are kept specially by the homoeopathic chemists: and the use of the Fly Agaric has been adopted by the school which they represent for curatively treating an irritable spinal cord, with soreness, twitching of the limbs, dragging of the legs, unsteadiness of the head, neuralgic pains in the arms and legs (as if caused by sharp ice), some giddiness, a coating of yellow fur on the lining mucous membranes, together with a crawling, or burning, and eruptive skin. In fact for a lamentably depraved condition of all the bodily health, such as characterises advanced locomotor ataxy, and allied spinal degradations leading to general physical failure. Just such a totality of symptoms has been recorded by provers after taking the fungus for some length of time in toxical quantities.

The tincture should be used of the third decimal strength, five drops for a dose twice or three times a day with a spoonful of water; or the trituration of the third decimal strength, for each dose as much of the powder as will lie on the flat surface of [370] a sixpence. Chilblains may be mitigated by taking the tincture of this Agaric, and by applying some of the stronger tincture on cotton wool over the swollen and itching parts at night.

"Muscarin" is the leading active principle of the Fly Agaric, in conjunction with agaricin, mycose, and mannite.

It stimulates, when swallowed in strong doses, certain nerves which tend to retard the action of the heart.

Both our Fly Agaric and the White Agaric of the United States serve to relieve the night sweats of advanced pulmonary consumption, and they have severally proved of supreme palliative use against the cough, the sleeplessness, and the other worst symptoms of this, wasting disease, as also for drying up the milk in weaning.

Each of these fungi when taken by mistake will salivate profusely, and provoke both immoderate, and untimely laughter. When the action of the heart is laboured and feeble through lack of nervous power, muscarin, or the tincture of Fly Agaric, in a much diluted potency will relieve this trouble. The dose of Muscarin, or Agaricin, is from a sixth to half a grain in a pill. These medicines increase the secretion of tears, saliva, bile, and sweating, but they materially lessen the quantity of urine.

Belladonna is found to be the best antidote.

Abstract

Objectives

To report the frequency and clinical outcomes of *Amanita phalloides* poisoning in the Australian Capital Territory and New South Wales, and the treatments used (including silibinin).

Design, setting and patients

Retrospective case series of patients admitted to public hospitals in Canberra and Sydney for suspected *A. phalloides* poisoning between 1999 and 2012 (identified from hospital records and calls to the New South Wales Poisons Information Centre).

Main outcome measures

Frequency of poisoning and the clinical outcomes.

Results

Twelve patients presented with a history suggesting *A. phalloides* poisoning, 10 with probable poisoning and two with possible poisoning. Eight of those with probable poisoning developed significant hepatotoxicity and four died. Silibinin was administered to nine of those with probable poisoning (the other presented before 2005). Maintaining silibinin supply became a challenge during two clusters of poisoning. Eight of the patients with probable poisoning were not long-term residents of the ACT, and six were immigrants from Asia.

Conclusions

The mortality rate due to *A. phalloides* poisoning in this case series was high despite treatment according to current standards, including use of silibinin, and the frequency of hepatotoxicity was more than double that for the previous decade. Ongoing public health campaigns are required.

Amanita phalloides ("deathcap" or "whitecap") is a cyclopeptide variety of mushroom that is responsible for more than 90% of mushroom-related fatalities; one mushroom cap can cause fulminant hepatic failure and death in an adult.[1] Most reported *A. phalloides* poisonings occur in Europe. In Australia, most occur in Canberra as *A. phalloides* grows in the Australian Capital Territory, particularly in the older suburbs of Canberra (which has been attributed to imported oak trees). Cases have also been reported in Victoria. Public health campaigns are commonplace in the ACT in summer and autumn ("mushroom season").

Amatoxin is the most potent hepatotoxin in cyclopeptide mushrooms; it irreversibly binds to RNA polymerase II, causing hepatic necrosis.[1] The clinical features of *A. phalloides* poisoning are well described (Box 1). The most recent report of *A. phalloides* poisonings in Australia was from the ACT over 10 years ago, describing seven poisonings that occurred between 1988 and 1998.[5] Since then, a chemically modified derivative of silibinin (silibinin-C-2',3-dihydrogen succinate, disodium salt [Legalon SIL, Madaus], referred to hereafter as silibinin) - a purported antidote to *A. phalloides* poisoning that is derived from the milk thistle *Silybum marianum* - has been stocked by hospitals in the ACT. In 2005, Canberra Hospital imported silibinin for use as an antidote through the Special Access Scheme of the Therapeutic Goods Administration because it is not registered for use in Australia. Sufficient stock was purchased to treat one patient for at least 96 hours at a dosage of 20 mg/kg/24 h, given in 6-hourly doses. This decision was made (despite a lack of good-quality evidence of efficacy) because there was no approved treatment in Australia, there was a plausible mechanism of action and some supporting evidence from animal studies, and silibinin is regarded as the standard of care in Europe. In 2010, the silibinin stock level at Canberra Hospital was increased so that there was sufficient stock to treat two patients and, in Sydney, Royal Prince Alfred Hospital also stocked it.

Here, we review cases of *A. phalloides* poisoning that occurred in the ACT and New South Wales between 1999 and 2012, including patients treated with silibinin.

Methods

We reviewed the clinical records of patients with possible *A. phalloides* poisoning who were treated at public hospitals in Canberra and the Australian National Liver Transplantation Unit at Royal Prince Alfred Hospital between January 1999 and May 2012. Patients were identified from clinical databases in departments of emergency medicine and clinical toxicology in the ACT and from call records of the New South Wales Poisons Information Centre. A diagnosis of *A. phalloides* poisoning was suspected on the basis of a history of mushroom ingestion and subsequent delayed onset of gastroenteritis and hepatitis; blood tests confirming the presence of amatoxin are not available in Australia.

1 Clinical features of acute *Amanita phalloides* poisoning[1-4]
0 to 6-18 hours after ingestion: Asymptomatic
6-24 hours after ingestion: Gastroenteritis, including abdominal pain, nausea, vomiting, diffuse diarrhoea, dehydration with or without hypotension, metabolic acidosis and electrolyte disturbance; normal or mildly deranged renal function and levels of hepatic enzymes
1-7 days after ingestion: Resolving gastrointestinal symptoms, but progressive hepatic failure, coagulopathy, kidney injury (including hepatorenal syndrome); possible progression to multisystem organ failure and a 10%-30% mortality rate
> 7 days after ingestion: Complete resolution of symptoms occurs in most survivors over weeks or months; chronic hepatitis may persist

De-identified demographic, clinical and treatment data were extracted and two prognostic tools for predicting death (or liver transplant) due to acute *A. phalloides* poisoning were considered.

Onset of diarrhoea < 8 hours after mushroom ingestion or INR ≥ 6 on Day 4. These criteria are supported by a study of 27 patients (sensitivity 1.0 and specificity 0.68 for diarrhoea; sensitivity 1.0 and specificity 1.0 for INR)[2] and a study of 10 patients (sensitivity 1.0 and specificity 1.0 for diarrhoea; sensitivity 0.71 and specificity 1.0 for INR),[6] but they have been criticised because the supporting studies classified liver transplant recipients as deaths in their analysis.[7]

INR ≥ 2.5 and serum creatinine level > 106 µmol/L from Day 3. The reported predictive utility of these criteria is variable (sensitivity 1.0 and specificity 0.98 in a study of 198 patients;[8] sensitivity 0.75 and specificity 0.90 in a study of 27 patients;[2] sensitivity 0.57 and specificity 1.0 in a study of 10 patients[6]).

Ethics approval

This study was approved by the Human Research Ethics Committees of ACT Health, Calvary Health Care ACT, Royal Prince Alfred Hospital and the Children's Hospital at Westmead.

Results

Over the 12-year study period, 12 patients presented with a history suggesting *A. phalloides* poisoning; they all developed clinical features of poisoning and were admitted to hospital (Box 2). The median age of the patients was 36 years (interquartile range, 27-51 years; range, 2-88 years) and eight patients were male. Eight of those with probable poisoning (based on clinical and mycological features) were not long-term residents of the ACT and seven were immigrants (six from Asia, one from Europe).

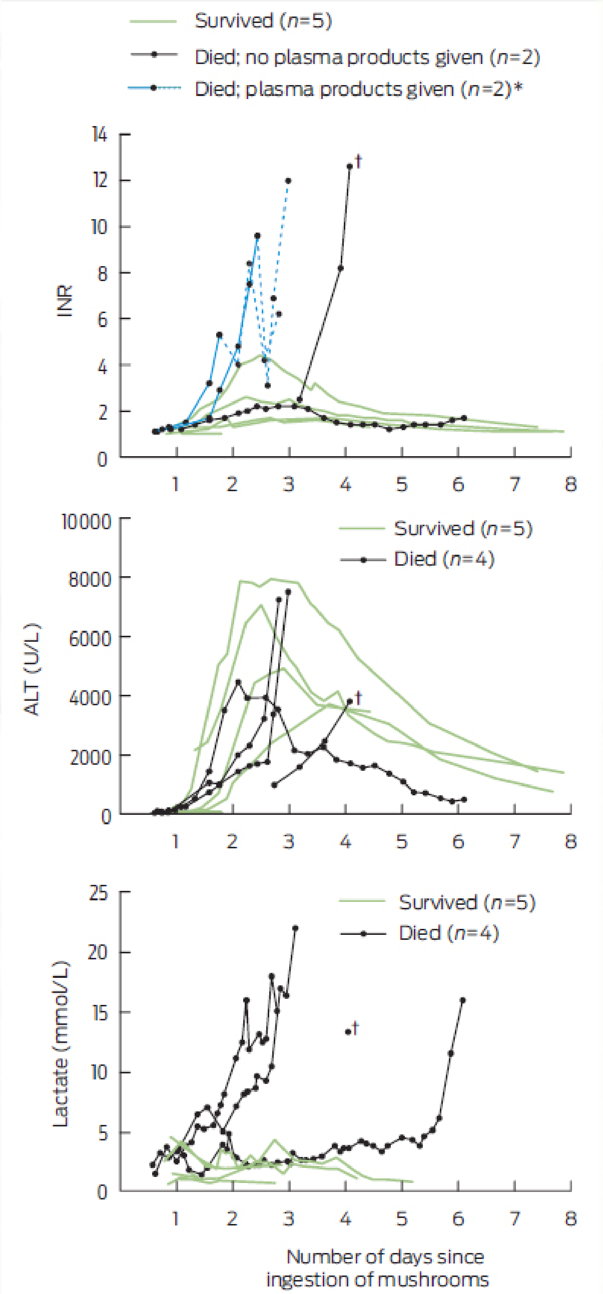
ALT = serum alanine aminotransferase (reference interval, < 55 U/L).
Cr = serum creatinine (reference interval, 60-110 µmol/L).
ICU = intensive care unit.
INR = international normalised ratio (reference interval, 0.8-1.2).
IV = intravenous.
La = blood lactate (reference interval, < 2.5 mmol/L).
MDAC = multiple doses of activated charcoal.
NAC = acetylcysteine.
* Poisoning was probable in Patients A-J (clinical or mycological features confirmed that *A. phalloides* had been ingested) and possible in Patients K and L (very mild symptoms and non-significant biochemical changes).
**Based on prognostication tools.
*** Patient G presented before 2005, so did not receive silibinin.

All the patients had ingested wild mushrooms. One had presented to a Sydney hospital after picking mushrooms in Canberra, transporting them home and then incorporating them into a meal. Two had consumed mushrooms for recreational purposes after they had been misidentified as a hallucinogenic variety. Another had consumed mushrooms believed to be *A. phalloides* (based on information in public health campaigns) for self-poisoning.

Two patients had very mild symptoms and non-significant biochemical changes, so *A. phalloides* poisoning was considered possible. The other 10 had probable *A. phalloides* poisoning owing to marked symptoms and the characteristics of the ingested mushroom; eight developed significant hepatotoxicity (alanine aminotransferase [ALT] level more than 10 times the upper limit of the reference interval) and seven were admitted to an intensive care unit. One patient presented to hospital after 48 hours of gastroenteritis but the history of mushroom ingestion was not noted until about 4 hours before she died. Six patients were transferred from the ACT to the Australian National Liver Transplantation Unit in Sydney. Four of the patients with probable *A. phalloides* poisoning died.



3 Temporal changes in INR, serum ALT levels and blood lactate levels in patients with probable *Amanita phalloides* poisoning.
ALT = alanine aminotransferase.
INR = international normalised ratio.
* Change from solid blue line to dashed blue line indicates start of treatment with plasma products.
† Time of ingestion unclear, so times are estimates.

Temporal changes in INR, serum ALT levels and blood lactate levels are shown in Box 3. In most patients, marked changes in INR and ALT levels did not occur until at least 24 hours after mushroom ingestion. In two of the patients who died rapidly, the rate of increase of INR was more marked compared with that in survivors, but the same was not observed with ALT levels. The rate of increase in blood lactate levels was also more marked in patients who died compared with those who survived. The onset of increased INR and ALT levels appears to have been delayed for one of the patients who died and had not received silibinin (Patient G); however, the time of mushroom ingestion by this patient was imprecisely documented.

Multiple therapies were administered, including silibinin to all but one patient with probable *A. phalloides* poisoning. Silibinin supply was exhausted during the treatment of one patient, who was subsequently given oral silymarin (Legalon [140 mg silymarin capsules], Madaus; a standardised extract of milk thistle seeds that contains silibinin). Other purported antidotes that were administered included intravenous acetylcysteine (given according to dosing guidelines for paracetamol poisoning) and intravenous penicillin (given in high doses [0.25-1.0 million units/kg/day]). Patients also received multiple doses of activated charcoal (50 grams 6-hourly by enteral administration).

Maintaining a supply of silibinin to treat patients was a challenge due to the clustering of events. Of the 10 probable poisonings, nine occurred over the last 4 years of the study period. In six of these cases, the patients presented on a public holiday (New Year's Day) - two on one occasion and four on another. Additional stock was urgently required for the cluster of four patients, which required close communication with pharmacy, clinical toxicology and liver transplant centre colleagues in other states, and with the importing company (which promptly mobilised sufficient stock). However, one of only three hospitals that stocked silibinin during the study period is in South Australia, but this was not known by anyone within the Poisons Information Centre network when treatment for the cluster of four patients was urgently being sought.

From our experience, elevated INR and blood lactate levels appeared to be the best prognostic markers. Other prognostic tools (listed in the Methods) did not provide useful advance warning of death - they met criteria only within several hours of death in the four patients who died. One death is notable because the INR values and ALT levels suggested resolution of hepatic injury, but the patient had progressive severe metabolic acidosis and hypoalbuminaemia and, 6 days after mushroom ingestion, developed an acute abdomen and subsequently died of cerebral oedema. The three patients who died rapidly with hepatic failure also had very severe lactic acidosis (Box 3). Severe gastrointestinal tract toxicity may be a significant contributory cause of death and may complicate liver transplantation.[9] Toxicity progressed rapidly in two patients who were thought to have ingested the largest doses (about 8- 10 mushrooms). Because of the small number of patients, it was not possible to explore the effectiveness of treatments.

Discussion

This case series shows that *A. phalloides* poisoning is an ongoing public health concern. It is also the first report of silibinin use in Australia for *A. phalloides* poisoning. Despite availability of silibinin, multiple ingestions from 2000 to 2012 led to severe poisoning, including four deaths. Compared with data from the previous decade,[5] the number of patients with hepatotoxicity more than doubled and the number of deaths quadrupled. However, the events were clustered and sporadic. People who do not reside in the ACT appear to be at higher risk, as do immigrants (six victims had recently arrived from Asia, where consumption of wild mushrooms is commonplace, and had limited English language skills). Those who consume mushrooms for recreational purposes may also be vulnerable.

Ongoing review of public health campaigns and existing treatment protocols is occurring and appears to be warranted. However, increased awareness of the toxicity of *A. phalloides* may have the counter-effect of prompting its use for self-harm, which is concerning given the low efficacy of existing treatments.

The approach to treating patients with suspected *A. phalloides* poisoning includes prompt consideration of the diagnosis and identification of the mushroom if a fresh specimen or a sample of gastric contents is available. This requires liaison with a mycologist and performance of the Meixner test. The Meixner test is conducted by adding hydrochloric acid to a sample of mushroom placed on newspaper; a blue colour change suggests the presence of amatoxin, although false positive results have been reported.[1] Treatment includes supportive care and gastrointestinal decontamination, and antidote use should be considered.[10] Fluid resuscitation is required during the gastroenteritis phase to restore haemodynamic stability and maintain renal perfusion. Amatoxin is subject to enterohepatic recirculation, so multiple doses of activated charcoal should be given to limit reabsorption. Nasobiliary drainage has also been employed to reduce enterohepatic recirculation.[11] Extracorporeal treatments have been trialled, but efficacy is inadequately quantified.

Electrolyte abnormalities should be corrected, and liver enzyme levels, INR, and lactate levels should be monitored for prognosticative purposes. Indications for liver transplantation are debated. Where possible, transplantation should be delayed until at least 2-4 days after poisoning to allow elimination of amatoxin to prevent graft poisoning.[12] Early predictors of severe poisoning (but not necessarily death) may also help decision making regarding transfer to specialised liver units.

Multiple antidotes are currently used to treat patients with *A. phalloides* poisoning.[1,10] The evidence of efficacy is limited for all treatments, largely due to the difficulties associated with human studies of an infrequent and sporadic type of poisoning. Two analyses of observational studies in human poisonings have supported the role of silibinin and acetylcysteine;[10,13] however, positive findings are limited by potential publication bias.[10,13] None of the treatments have been subjected to dose-response or controlled trials in humans. Many animal studies are of limited clinical relevance because treatments are not delayed. Further, in-vitro studies have demonstrated effects of benzylpenicillin, acetylcysteine and silibinin in human cultured hepatocytes,[14-16] but not canine hepatocytes.[17] A study in pigs demonstrated no beneficial effects of silibinin, acetylcysteine, benzylpenicillin, cimetidine or thioctic acid administered 4 hours after poisoning.[18] In our case series, four out of 10 patients with clinically significant poisoning died, despite the use of intravenous silibinin and other treatments in nine of them. The optimal doses and timing of antidotes, and the range of amatoxin ingestion for which antidotes are effective, are unknown.

Despite these limitations, silibinin continues to be imported into Australia and is widely used elsewhere. Decisions regarding stock holdings of silibinin require consideration of cost (about $1400/day/patient), stock expiration, and time to obtain replacement or additional stock (potentially long, as it is not marketed in Australia). Our experience suggests that Poisons Information Centre knowledge of silibinin stocks, and rapid communication with the distributor and hospitals is required. A coordinated national approach (eg., a national inventory of antidotes) may be useful given that *A. phalloides* poisoning is not limited to the ACT.

A blood test that detects amatoxin would be useful to confirm exposures for epidemiological purposes. If rapidly available, a quantitative assay might assist existing prognostic tests, although more research is first required to guide interpretation of these results - for example, to develop a nomogram for risk stratification, similar to the approach used for paracetamol poisoning. An amatoxin assay may also be useful for determining when the blood concentration of amatoxin is sufficiently low in an individual patient to allow liver transplantation to proceed, when required, without subsequent poisoning of the graft.

Management is controversial in patients who present early after ingestion of mushrooms that may be *A. phalloides* but do not have clinical features of significant poisoning. We identified two such patients with favourable outcomes (although *A. phalloides* ingestion was not confirmed). In such cases, the risk of *A. phalloides* ingestion should be clarified by consulting a mycologist and/or conducting a Meixner test. Early intervention, including decontamination and antidotes, should be considered after consulting a Poisons Information Centre.

Clinical trials on antidotes for *A. phalloides* poisoning would be extremely helpful as there are no treatments with good evidence, and there may be as yet unknown but cheaper and more widely available alternatives to silibinin. An observational study of silibinin (ClinicalTrials.gov Identifier, NCT00915681) is underway, but no randomised controlled trials are currently registered and most guidelines follow the accepted standard practice in Europe.

A. phalloides poisoning is a public health problem in Australia, particularly the ACT, and the mortality rate is potentially high. Based on currently available data, we recommend treatment with supportive care, multiple doses of activated charcoal, intravenous silibinin, and acetylcysteine, as well as consideration of liver transplantation.

Early man was profoundly moved by the apparently miraculous attributes of lightning and thunder which first inspired in him fear, then respect and reverence for the power his gods displayed in those awesome phenomena. Of particular concern to the ethnomycologist is the causal association in the mind of primitive man of thunderbolts and mushrooms and among the cultures in which this magical alliance became integrated into national mythologies were the Roman and the Hindu. In Roman lore, some fungi were believed to spring from the ground in places struck by a thunderbolt and according to Hindu tradition as recorded in the Rig Veda, it is stated that "Parjanya, the god of thunder was the father of Soma" (Wasson, 1969). Wasson minutely examined the available evidence for the identification of soma and concluded that the most convincing interpretation we may hope for at present is its identity with *Amanita muscaria* (L. ex Fr.) Hooker.

During the past several years, I have examined some aspects of ethnomycology in the Americas, principally those relating to mushroom stones and Maya codices (Lowy 1968, 1971, 1972a, b). As a result of a study made in Guatemala, Mexico, and Honduras in June and July, 1973, it was established that there exists in the Guatemalan highlands and in southern Mexico a tradition that links *Amanita muscaria* with the thunderbolt. Preliminary inquiries in western Honduras have thus far failed to reveal a trace of this legend, nor have I found it in El Salvador. The first intimation that such a mythology might be extant among indigenous peoples of the Americas came in 1970 in the course of my field work in Mexico and Guatemala. Although I had by that time compiled a small mushroom vocabulary in several Indian languages, further opportunities were sought for the verification of the meanings of some words from other native informants and through consultation with professional linguists. Sufficient evidence is now at hand to justify the assertion that in some regions of the New World the *Amanita muscaria*-thunderbolt legend is firmly implanted in the minds of its autochthonous inhabitants.

While I was interrogating three young bilingual (Quiche-Spanish speaking) Indians who were participants in the linguistic "Proyecto Francisco Marroquin" in Antigua, Guatemala in June, 1973, these in formants unequivocally identified *A. muscaria* from a color photograph. Their name for this mushroom in the Quiche idiom was "kaquljá :." When asked what the word meant, they translated it into Spanish as "trueno" meaning thunder. After consultation among themselves and questioning by myself and Dr. William Norman, Quiche specialist, it was evident that it was not thunder alone that was signified by "kaquljá :," but the accompanying lightning as it strikes the ground during a storm. The equivalent term in Spanish is "rayo." This was clearly differentiated from the Quiche word "xkoyopá :'," or "relampago" in Spanish, a lightning flash, which, according to my informants, was never used to designate the mushroom. It is of interest too, that the native speakers could offer no explanation for the use of the word "kaquljá :" for *A. muscaria*, indicating only that it was common usage. Its ancestral origins have long since been forgotten. To my knowledge, this is the first report that the thunderbolt and *Amanita muscaria* have been found to be intimately related in the folklore of an indigenous population in the Americas.

At the "Proyecto," *Amanita caesarea* (Scop. ex Fr.) Pers. ex Schw. was easily recognized from my color photograph by the native speakers of Quiche, Cakchiquel, and Mam. It was called "q'atzu :i" (or by one of its variants "atzui" or "atzu") by the Quiche, a word which I had confirmed on many previous occasions in the Quiche-speaking regions of Guatemala. Among the Cakchiquel of Solola and Panajachel, *A. caesarea* is known as "q'uatzu :y" which was verified by Dr. Norman's Cakchiquel group at the "Proyecto." Lic. Nora England, specialist in the Mam language there, kindly allowed me to question her native Mam students and from them the word "xq'antzy:" was given for *A. caesarea*, but a photograph of *A. muscaria* was not recognized by them. The Cakchiquel group also identified *A. muscaria* from the photograph, knew it to be poisonous and called it "ruk'awach q'uatzu:y," the poisonous "q'uatzu :y," but no other connotation was associated by them with this mushroom.

A few kilometers north of Chichicastenango, in pine woods along the road to El Quiche, I again collected (July, 1973) both *A. muscaria* and *A. caesarea* and returned with the specimens to the Sunday market at Chichicastenango. There I sought the mushroom venders and displayed my finds. The edible and poisonous species were immediately distinguished and I was strongly admonished not to eat the "kaqulјá :" for it would have fatal consequences. Whereas "kaquljá :" refers to the legendary origin of *A. muscaria*, a Quiche expression that is descriptive of its dangerous, fearful potentialities is "itzel ocox," meaning the evil or diabolical mushroom.

In Comitán, San Cristóbal de Las Casas, and Tuxtla Gutiérrez in the state of Chiapas, Mexico, *A. caesarea* is a common and highly prized mushroom called "yuyo" (or "yullo") which in some regions of Latin America is a term used to signify "hierbas tiernas comestibles" (in "Diccionario de la lengua Española", Madrid, 1970), tender edible herbs. It is frequently prepared by roasting over a charcoal fire and I have eaten it in public places in San Cristóbal on numerous occasions. Incidentally, I have consistently found in my travels throughout the Americas that among lay individuals with a formal education, varying degrees of mycophobia is the general rule, but the educationally less privileged tend to be distinctly mycophilic. This is not as paradoxical as it may appear, since the peasantry are closest to the soil and know at first hand its products both cultivated and wild. *Amanita muscaria* is well known as a poisonous mushroom throughout the region of Chiapas under discussion and the revealing Spanish epithet for it in San Cristóbal de Las Casas and in Tuxtla Gutiérrez is "yuyo de rayo," the "yuyo" of the thunderbolt. I also discovered that among the Tzeltal-speaking natives of San Cristobal and nearby Zinacantán, this expression has its exact counterpart in their language. *Amanita muscaria* is called by them "yuy chauk," "yuy" being a variant of the Spanish "yuyo" and "chauk" meaning "rayo" or thunderbolt.

Chiapas and Guatemala are not only geographically contiguous, but, more significantly, they share a common heritage, so it may be surmised that the similar mushroom mythologies that find expression there reflect the influence of a dominant Mayan civilization. It may only be conjectured how this legend came to be shared by such widely separated cultures as are those of the New World and the Indo-European, but it is not improbable that it arose independently among the Maya. Further inquiries among contemporary Guatemalan linguistic groups including the Cakchiquel, Kekchi, Mam, and Ixil in Guatemala and the Tzotzil, Tzeltal, Chontal, and others in Mexico are planned so that it may eventually be possible to trace the range and depth of this ancient tradition in the Americas.

Abstract

In the legendary biographies of some Buddhist adepts from the 2nd- and 9th-centuries there are some clues which can be interpreted to reveal that the adepts were consuming psychedelic *Amanita muscaria*, 'fly agaric', mushrooms to achieve enlightenment. This secret ingredient in the alchemical elixir they used to attain 'realization' was, of course, unnamed, in keeping with their vows to maintain the secrecy of their practices. Its identity was concealed behind a set of symbols, some of which appeared in the Soma symbol system of the Rg Veda, some other symbols possibly passed down from a time of earlier shamanic use of the mushroom in the forests of Northern Eurasia, and some symbols that may be unique to these Buddhist legends. The congruity of these sets of symbols from Northern and Southern Asian traditions will be shown to be reflected in the Germanic tradition in some characteristics of the Oldest God, Odin.

Keywords: Amanita muscaria; Soma; Buddhism; Psychedelic drugs; Odin.

1. Introduction

It has been put forth by various theorists and to different degrees of acceptance that the psychedelic mushroom *Amanita muscaria* (L. ex Fr.) Hooker var. *muscaria*, the fly agaric, is the real entity behind such myths and legends as Soma, both god and sacred beverage (Wasson, 1968), the apple in the Garden of Eden (Wasson, 1968) and the apples of Hesperides (Ruck in Wasson, 1986, p. 171), the Golden Fleece (Allegro, 1970, p. 118; Ruck in Wasson, 1986, p. 171) and the fire of Prometheus (Ruck in Wasson, 1986, p. 169), Kakulja hurakan 'Lightening bolt One-leg' of the Mayans (Lowry in Wasson, 1986, pp.47-51) and the Huitzilapochtli aspect of Tezcatlipoca of the Aztecs (Wasson, 1986, p.53), and even Jesus Christ (Allegro, 1970) and Santa Claus (Ott, 1976, p. 97).

The fly agaric seems to be more liberal regarding the varieties of mythological traditions it appears in than the few specific habitats it prefers in nature. I have recently found it appearing in the pages of some hagiographies of Buddhist *siddhas*, 'adepts, attainers' or, very loosely, 'saints'. No direct connection of any psychedelic mushroom to any Buddhist tradition has yet been demonstrated, but I present evidence here which shows that in a Buddhist alchemical tradition, probably a continuation of the Vedic soma use, *Amanita muscaria* was taken under certain conditions to achieve enlightenment.

According to Wasson (1968, p. 168), religious use of *Amanita muscaria* began some time after the last Ice Age in the northern Eurasian forest belt which spread north following the retreating polar ice cap, approximately 9000 B.C.E. There, probably beneath a birch tree, its preferred symbiont, early human foragers found and ate the magnificent red- and-white fly agaric, possibly after observing the effect it had on reindeer who had eaten it. Thus began the religious and recreational use of this psychedelic mushroom which continues to the present time in several regions of the world.

At some undetermined time, early Indo-European speaking tribes lived in close proximity to the ancestors of the Finno-Ugrians with whom they shared the use of fly agaric, along with a vocabulary pertaining to its use (for examination of the linguistic evidence of contact between these tribes, see Burrows, 1973, pp.23-27; Collinder, 1955, pp. xiii, 46, 128-141). Centuries later, priests of the Vedic culture sang hymns in praise of Soma the god, the sacred plant and the sacred drink pressed from the plant. For reasons that remain uncertain, fly agaric was later replaced in Vedic Soma ceremonies by non-psychedelic substitutes, and its true identity became a mystery even to the previous keepers of this secret, the Vedic priests.

After that point, there seem to be no references recorded in Indian literature by those who had practical knowledge of the true identity of Soma, or by those possibly consuming fly agaric under another name. The references to Soma in post-Vedic sources are discussed by O'Flaherty (Wasson, 1968, pp. 95-147).

2.1. The hagiographies of Buddhist siddhas

Yet, such references to practitioners of religious rituals actually using the psychedelic mushroom do exist. I have found them in *The Stories of the Eighty-Four Siddhas* (Skt. *Caturasiti-siddhapravrtti*, Tib. *Grub thob brgyad cu rtsa bzhi'i lo rgyus*) which was translated into Tibetan and written down in the late 11th- or early 12th-century C.E. by the monk Smon-grub-shes-rab, as narrated to him in Sanskrit by Abhayadatta. The attribution of author, translator and origin of the text given in its colophon does not mention an original Sanskrit text as a source. This conspicuous omission may suggest derivation from oral tradition. A discussion of the identities of the purported author and translator can be found in Dowman (1985, pp. 384-88).

The most likely sources of the eighty-four thumb-nail biographies that make up this work were the legends of each of the *siddhas* which were passed down as oral hagiography by his or her disciples and later compiled, possibly by Abhayadatta who did not include a record of his sources.

There are two English translations of this work, Robinson (1979) and Dowman (1985). Both translators worked under the guidance of Tibetan lama advisors. Robinson's translation is very close to the Tibetan text, but Dowman presents a self-described adaption 'from the stilted mnemonic style of the Tibetan manuscript to give a fluent idiomatic rendering into English while maintaining fidelity to the original meaning' (Dowman, 1985, p. xii). At least in the story of the *siddha* Karnaripa, Dowman and his lama advisors completely missed the 'original meaning'. This story, which reveals the identity of the secret ingredient of the alchemical elixir which brings enlightenment, is interpreted by Dowman simply as a parable of the *siddha*'s humility and modesty! Robinson also fails to reveal the real meaning of the story of Karnaripa, which is not explicitly expressed in the story, but he does not obscure the real meaning with imperceptive, misinformed impressions. I present my own translation of the story of the *siddha* Karnaripa below. I have tried to keep my translation as close as possible to the literal content of the Tibetan text, so that those who do not read Tibetan can interpret for themselves the imagery and symbolic elements of the story.

3. Method

3.1. Interpretation of the secret meaning

There are at least three levels of information contained in the eighty-four stories. Firstly, there are the historical, biographical facts: the castes into which the *siddhas* were born, their occupations, the locations they lived in, the names of their gurus and the tantras they practised. The validity of these facts is, in many cases, uncertain.

The second level of meaning in these stories is the didactic. For instance, Karnaripa is told by his guru that he should not receive tasty food as his alms; he should only accept as much food as will fit on the point of a needle. The lesson for Karnaripa and for readers of his story is that tantric disciples should practice austerities. This level of meaning is carried in the stories by the overt meaning of the words and symbols.

In many stories, I cannot say how many, there is embedded a deeper level of meaning which is expressed in *sandhabhasa*, 'intentional language' or 'enigmatic language', which is used to obscure the true meaning for the uninitiated while declaring it for the initiates. Such symbols in the stories seem to mean one thing, but they really mean something else. After receiving Nagarjuna's dietary advice, Karnaripa returns from begging with a pancake piled with sweets on the tip of his needle. This seems to be an ironic joke played on his guru by his benefactors. However, at a deeper level which I will attempt to interpret below, the pancake on a needle is a symbol representing the fly agaric mushroom. After all, we should not expect practitioners of tantra or alchemy, known for their vows of secrecy, to relate a story of the wonderful alchemical elixir which grants enlightenment, while plainly and openly stating the identity of the secret essential ingredient.

It would be difficult to determine the degree to which these legends accurately report the events in the lives of the *siddhas*. It could be said that this collection was intended as a didactic paradigm of the variety of paths on which human beings wander in samsara and the corresponding paths which lead them to enlightenment. Karnaripa was also known as Aryadeva. The events in his life as told by Abhayadatta are very similar to those details given by the Tibetan historians Bu-ston and Taranatha, but all of these authors are also unanimous in their error of conflating the biographies of two Aryadevas, who lived five centuries apart.

As I have no explanation myself, I would love to know why the religious use of a psychedelic mushroom is, according to my interpretations, attributed to two Buddhist saints, one a 2nd-century Madhyamika dialectician and the other a 7th-century Vajrayana adept, both having the same name. The legend of Karnaripa was obviously composed by a practitioner, probably an accomplished practitioner, of *Amanita* alchemy, but, unless the legends are true, the reasons for connection of that tradition with the lives of the Aryadevas are not so obvious.

I realize that I cannot, based on the hagiographies by Abhayadatta, Bu-ston and Taranatha, prove that *Amanita* alchemy was practised by the specific persons named Aryadeva. However, even if it were true that these stories are allegorical paradigms having no other historical value, what would remain would be a record of anonymous Vajrayana Buddhist tantric adepts using psychedelic mushrooms, under certain circumstances, to become enlightened.

3.2. Siddha tradition

The *siddha* tradition flourished in India from the 8th- to the 12th-century. In place of intellectual and academic efforts, it emphasized the dedicated practice of Tantric meditation under the guidance of an accomplished guru which would result in the practitioner's attainment of the Great Seal (Skt. *mahamudra-siddhi*, Tib. *phyag rgya chen po'i dngos sgrub pa*). This was the expression used to refer to the state of enlightenment they attained through their varieties of tantric meditation.

Ten of the *siddhas* were monks or yogins who had not found realization through monastic and scholastic endeavors. Others lacked concern for realization of the Dharma until each of them reached a crisis in his or her life. They found gurus who showed them the means to free themselves from the snares of *samsara*, i.e. 'to obtain the *siddhi* of *Mahamudra*'. These means were the practices of tantric meditation, often specifically adapted by their gurus to match the specific problems of their life crises. However, in the case of Karnaripa/Aryadeva, it seems that many initiations by various masters could not bring realization to him, in spite of his auspicious birth and his excellence in Buddhist academic studies. He needed to drink an alchemical elixir to allow realization to arise in him.

3.3. The story of the siddha Karnaripa

This *Mahasiddha* Karnaripa, whose story is number eighteen in the *Stories of the Eighty-Four Siddhas*, is actually two different persons whose biographies are conflated and undifferentiated in Tibetan sources. No distinction is made in works attributed to Aryadeva in the Tibetan canon, although the subject of any of the works usually falls into the area of study of one or the other Aryadeva.

The Sanskrit name Aryadeva appears as 'Phagspa-lha in Tibetan; Cheng t'ien (translated) or T'i po (transliterated) in Chinese; and as Shoten (translated) or Daiba (for Deva) in Japanese. These are usually translated as 'Sublime god' (Malalasekera, 1966, p. 109). I will offer an alternative translation below. For reasons which are given in his biographies, overtly as a cover story and covertly as encrypted tantric secrets, he is also known as Karnaripa or Kaneripa. Alternative renderings are most likely due to scribal errors. In the text of the story of Karnaripa which I have translated, his name is given as 'Kartaripa' in the first two references, there after being given as 'Karnaripa' seven times, 'Aryadeva' also being used four times, and 'Mig-gcig-pa' being used one time. Fig. 1 is a reproduction of the text which appears on ff. 96-102 of *Grub thob brgyad bcu rtsa bzhi'i chos skor*, (Chophel Legdan, 1973) also reproduced in Robinson (1979, pp. 335-337).

Fig. 1. The Story of the Siddha Karnaripa from The Stories of the Eighty-four Siddhas by Abhayadatta (ca. 1100 C.E.). Courtesy of Dharma Publishing.

The '*-pa*' suffix to the Sanskrit is an abbreviation for '*-pada*', an honorific affix. The '*Karnari-*' part of his name has been considered to be of uncertain translation, although it must derive from '*kana*' (Monier-Williams, 1899, p. 269) which is the Sanskrit equivalent of his Tibetan name Mig-gcigpa, 'One-eyed'.

The first Aryadeva was the most eminent disciple of Nagarjuna, the founder of the Madhyamika school of Buddhism. He lived in India in the 2nd century C.E.

The second Aryadeva was the disciple of the Vajrayanist *Mahasiddha* Nagarjuna who had several disciples counted among the eighty-four *siddhas*. Aryadeva II lived in India in the 7th- or 8th-century C.E.

A detailed examination of the conflated biographies and the canonical works attributed to 'Aryadeva' appears in Malalasekera (1966, pp. 109-116) (This source does not refer to *The Stories of the Eighty-Four Siddhas*). I have begun an examination of the works of both Arydevas, their gurus and fellow disciples, in search of further references to their use of psychedelic mushrooms. However, as of this writing, I have been limited to finding such references in their Tibetan hagiographies and have been surprised to find evidence linking both of the Arydevas and the later Nagarjuna and some of his tantric disciples to the use of psychedelic mushrooms.

What follows is my translation of the story of Arydeva from *The Stories of the Eighty-Four Siddhas*, with my interposed interpretations of the *sandhabhasa*. The reader might enjoy a preliminary reading of the story itself by skipping over the interpretive sections.

3.4. Karnaripa's miraculous birth

In order to avoid interrupting the story after the very first line, I shall do so even before the story begins. In the Buddhist view, there are four kinds of births (or rebirths) which result in existence in the world of living beings. These are birth through heat and moisture for plants and lower life forms, birth from egg for oviparous life forms, birth from womb for viviparous life forms and miraculous birth for beings from higher realms who appear in the world of living beings in human form in the center of a lotus blossom, uncontaminated by passage through a womb. Karnaripa and two other *siddhas*, Pankaja and Sakara, are described as being miraculously born. The story of Sakara contains some symbols that may be references to *Amanita muscaria* and these will be discussed below.

In many cultures, mushrooms themselves were considered to be miraculously born, due to their mysterious, apparently seedless generation. Wasson (1971, p. 184) explains the significance of the name of the deity Aja Ekapad who appears in the Rg Veda closely associated with Soma. Aja 'un-born' and Ekapad 'single foot' refer to the mushroom's miraculous birth and the monopod stem upon which it stands. Karnaripa's miraculous birth is one of several clues to his connection with the mushroom, though not the most persuasive.

3.5. The story of Mahasiddha Karnaripa

Of the four ways of birth, his was miraculous. He went away to glorious Nalanda college. He became principal of all monks. There were one hundred-thousand scholars. Although he requested instruction from many masters, realization did not arise. He heard report that Master Nagarjuna resided around the southern regions. Special faith and adherence arose in him. He entered on the road and went.

At the shore of a great ocean, Sublime Manjusri had transformed himself into a fisherman living there. Karnaripa saw him, bowed and offered him a *mandala* and said, 'Because it is reported that Master Nagarjuna lived around the southern regions, Oh Honored One, please show me the road'. The fisherman said, 'He resides inside that thick forest over there practising alchemy'. Having been instructed thus, Karnaripa went there. He saw the master dwelling there, collecting alchemical materials and preparing them. Karnaripa bowed, made a prayer, respectfully asked to be accepted as a student; his request was granted. He was given initiation and instruction in the *mandala* of *Guhyasamaja* and sat in meditation before the master.

Not very far from that forest was a city. Both master and pupil went there for alms. Karnaripa received very delicious alms, while the master received alms that were not delicious. The master said, 'Because this food of yours was given by lustful women, it is not delicious. This obtaining of delicious food by you is not good, so do not collect it on a tree leaf, but receive it on the point of a needle'. Doing so, Karnaripa took a single piece of rice pulp and ate it.

In the morning, women made wheat cakes, put various kinds of delicious food on a cake, put it on the point of a needle, and brought it to Karnaripa, who brought it to his lama. Nagarjuna ate it and said, 'What did you do to receive this?'

Karnaripa said, 'Doing just as my lama said, your worship, I received this'.

'Well then do not go to the city; stay at home'. Nagarjuna said.

3.6. Delicious food, pancake on a needle

A common epithet for Soma in the Rg Veda is *madhu*, 'honey, sweetness, delicious, intoxicating'. *Amrta*, or Nectar of the gods, is idealized as the most delicious food and drink. The 'very delicious alms' that Karnaripa received might be a reference to this ambrosia. The image of the wheat cake on the tip of a needle with delicious food on top represents the flattened cap of the mushroom on the top of its stalk, flecked with white remnants of its 'universal veil'.

At this point in the story Nagarjuna thinks that this 'delicious food' (on the didactic or *sandhabasa* level?) is not good for Karnaripa, who eats instead 'a single piece of rice pulp' (Tib. '*bras chan*). In Monier-Williams (1899, p. 1249) under *soma*, after the primary definitions of god, plant and drink, we find '*somam* - rice pulp'. Here the true name of the elixir Soma may be encrypted in a Tibetan-Sanskrit pun.

Having been advised by Nagarjuna to stay home:

> Karnaripa did so, but when he stayed, a tree goddess brought much delicious food into the house and actually showed him her form. She bowed and conversed with him. He received her alms and brought them to his lama who said, 'Where did you obtain things like this?'
>
> Karnaripa said, 'It was brought by a tree goddess'. In order to test if this were true, the sublime master went to the tree possessed of the goddess, looked at it but did not actually see the form of the goddess. He saw her arm up to the shoulder.

3.7. The tree goddess

Although the exalted, sacred status of the birch tree and the central roles it played in the cosmology and shamanic rites of the Siberian and Altaic cultures were well documented in many examples compiled by Holmberg (1927) and Eliade (1964), the reason why the birch is thus regarded as the Tree of Life is not given by either author. It is given by Wasson (1968, pp. 216-218).

The birch tree (Betula sp.) is the preferred mycorrhizal symbiont of the psychedelic mushroom *Amanita muscaria*, and the preferred host of the shelf fungus *Fomes fomentarius*, which was boiled and dried to form perfect tinder to catch a spark for making fires. These two magic substances were found growing on or below the birch tree which was therefore the most important tree in the cosmos. Holmberg (1927, p. 350) gives a Mordvin tale of a giant birch tree growing on a hill in the depths of the forest, a tree with giant leaves and buds, roots which ring round the earth, and branches which surround heaven. At the root of this birch is a spring, roofed over with carved boards and white sheets, on its edge a red wooden can containing a sweet honey drink. The can has a silver ladle decorated on the bottom with the sun and the moon, the handle with smaller stars. As the sun moves in the heavens, the handle of the ladle turns with it.

The 'red can' can be interpreted as the red *Amanita* and the 'sweet honey drink' as the psychedelic essence. The 'ladle' is also the mushroom; its cap is a red solar disk by day and shines silver like a lunar disk in moonlight. Before the white flecks - remnants of the universal veil - are washed off the cap, they are the stars in the sky that turn as the stem is turned. Similar substance forms the ring around the stem.

Holmberg (1927, p. 351) also retells several Yakut legends of the Tree of Life. In one tale, 'the First Man' approached the magnificent tree to ask why he had been created. From an opening in the trunk there appeared a female, visible only to the waist, who told him he had been created to be the father of the human race. In a variant of this story, 'the White Youth' prayed to the 'Honored High Mistress', the spirit of the Tree of Life, to be granted the companionship of a wife and other human beings. The tree creaked and from under its roots the tree spirit arose up to her waist. She appeared as a middle-aged women with grave eyes, flowing locks and naked, swelling breasts which she offered to the Youth. He drank her milk and felt his powers grow a hundredfold.

Wasson (1968, p. 214) sees the tree goddess who appeared from under the roots as the *Amanita muscaria*; her swelling breasts he sees as the mushroom, her milk as the psychedelic essence.

In another Yakut tale, the tree goddess is called Kibai-Khotun, the goddess of Birth and Fate. The Yukaghir call the mushrooms *can-pai*, 'tree girl' (Wasson, 1968, p. 272). Common elements of these Siberian stories are: a sacred tree, a goddess of the tree who appears only up to her waist from the tree or its roots, the swelling breasts of the goddess and her milk of knowledge and strength, and a lake or spring under the tree.

This tree goddess from Siberian legends appears in the story of Karnaripa in South-East India. She does not appear to him as a legendary figure from a far away land, she appears to him in person. She shows to him her true form and brings him 'much delicious food'. Nagarjuna could only see her arm up to the shoulder; he saw the mushroom sticking out of the ground but not the goddess.

Wasson observes (1968, p. 218) that the sacred tree and the tree goddess were apparently absent from the Vedic Soma symbol system. This absence suggests that the *Amanita* alchemy tradition which Nagarjuna and Karnaripa practised was separate from the Vedic Soma tradition, or that such a separate tradition was synthesized with the Soma tradition by the Buddhist alchemists. Nebesky-Wojkowitz (1956, pp. 539-553) gives examples of the many similarities between Siberian shamanism and 'traditions and rites that appear to be survivals of an early Tibetan shamanism.' If, in the distant past, some exchange of shamanic practices did occur between Siberian, Mongolian and Tibetan people, it is unlikely that an element as important as the *Amanita muscaria* would not be a part of that exchange. I will discuss below a certain goddess who will be linked with the fly agaric, who seems to appear in the Siberian and Tibetan pantheons, but not in Indian tradition.

There is evidence that the birch as the Sacred Tree was not overlooked in India. In Monier-Williams (1976, p. 51) we find, among the synonyms for 'birch', *mahausadham* 'great drug'. Although the birch is regarded in some systems of herbal medicine to have some minor useful properties, these would by no means qualify the birch tree itself as a 'great drug'. It seems more likely that the great drug was the *Amanita muscaria*, the symbiont of the birch.

Coomaraswamy (1971, pp. 32-33) agrees that trees and tree deities played an insignificant part in the Rg Veda and Atharva Veda, but he says, 'There is no motif more fundamentally characteristic of Indian art from first to last then is that of the Woman and Tree'. Some of his examples even include a half-seen figure in the tree. I note the similarity to such figures from the Siberian myths and from Karnaripa's story, but I could find no other images from the fly agaric symbol set in any of Coomaraswamy's examples. A genealogy of these mythologies is needed. The goddess who appeared to the Buddha beneath the Tree of Enlightenment is worth investigating for any possible connection with the *Amanita* birch goddess.

As we return to the story of Karnaripa, Nagarjuna is trying to confront the tree goddess.

> The master said to her, 'You actually showed your form to my student, why do you not show it to me?'
>
> From the tree arose a voice like this, 'Obviously you have not abandoned a portion of your defilement; your student has entirely abandoned his defilement, so he saw me'. Thus she spoke.
>
> At that, the master and student conferred. They said, 'We need to eat the alchemical medicine'. The master gave it to Arydeva who was called Karnaripa. He himself also ate it.

3.8. Karnaripa Aryadeva

There is no explanation given for Karnaripa having another name 'Aryadeva', which first arises in this story at the point of the drinking of the alchemical elixir. 'Aryadeva' and its Tibetan equivalent 'Phags-pa-lha' are usually translated as 'Sublime god'. However, the initial elements of these names may be implied genitives (for Aryanam deva and 'Phags-pa'i-lha) which would translate as 'God of the Aryans', a perfect epithet for Soma who was, of course, a god of the Aryans. The meaning of 'Karnaripa', as will be shown below, is more definitely connected with Soma.

> Then Karnaripa smeared the elixir on a dead tree, causing leaves to grow. The master saw that, laughed a little, and said, 'Since you smear my elixir on the tree, bring my elixir, come!' So

> Karnaripa said, 'If you wish, I will give it'.
>
> He put his own water [i.e., he urinated] into the full water pot and stirred it with a stick so that it became a pot of elixir. He went straight to his master and offered it. The master said nothing to this. He sprinkled it on a dead tree which grew leaves. Thereupon the master examined whether or not realization had arisen in his student.

3.9. Magic urine elixir

Of all the plants in the world used by humans to alter their minds (I include not just the psychedelics but also the stimulants, cognodisleptics, narcotics, etc.), *Amanita muscaria* is the only such plant known to have the following characteristic: its active constituent, muscimol, is passed through the human body with only a small part of the dose destructively metabolized, so that the urine of the mushroom eater contains enough muscimol to be effectively recycled for up to five more intoxications. This quality of the fly agaric was known to its users in Siberia (Wasson, 1968, p. 25) and to some Indians of North America (Keewaydinoquay, 1979, pp. 29-31). Wasson (1968, pp. 25-34) claims to have discovered evidence in the Rg Veda that the Vedic priests were aware of the potency of the Soma-drinker's urine. This potency of the urine of the fly agaric eater is the property that will identify any unidentified drug which also has this characteristic.

The potency of Karnaripa's urine is demonstrated by its revitalization of the dead tree on which Nagarjuna sprinkled the urine. This was the same effect produced when Karnaripa smeared Nagarjuna's alchemical elixir on a dead tree. Also, in the words of the story, 'He put his own water into a full pot.., so that it became a pot of elixir'. The urine does not merely share similar characteristics with the elixir, it is the elixir.

And then, by observing the single fact that Karnaripa's urine had the same effect on the dead tree as his alchemical medicine, Nagarjuna determined that realization had arisen in his student. This is an unusual method for a Tantric Buddhist master to test the attainment of his student.

These references to the potent urine of the drinker of the alchemical medicine are very strong evidence that the fly agaric was an essential ingredient in the elixir.

The story does say that Karnaripa urinated 'into a full water pot (*chu rdzam gang gi nang du rang gi chu btang*)'. It seems necessary to ask, why does he urinate 'into a full water pot'? The 'full water pot' might be a reference to the 'full vessel' or 'brimming vessel' (*purna ghata*), 'the commonest of all Indian symbols of plenty' (Coomaraswamy, 1971, p. 40). And also 'when soma is represented in art, it is as a full vessel' (Coomaraswamy, 1979, p. 40). Is Karnaripa's urination into the full water pot another Tibetan-Sanskrit play on words which refer to Soma or is this just a meaningless coincidence?

3.10. Laughter

I must discuss the occurrence of Nagarjuna's laughter in the story, occurring after they drink the elixir. His laughter might suggest the elixir has exhilarating effects, in addition to its rejuvenating effects and its unexplained powers to cause 'realization' to arise. This occurrence of laughter is one of only four occurrences of laughter in all eighty-four biographies, and possibly the only one of its kind, i.e. euphoric, exhilarated laughter.

In his own legend, *Siddha* Virupa laughs 'twelve wrathful laughs' to subdue a legion of witches who were trying to kill him. This is laughter of a different sort. In the story of *Siddha* Bhusuku, the king and the people laugh at Bhusuku because he had been a lazy bum and yet stood before them to lecture them. This is clearly derisive laughter.

Finally, in the story of *Siddha* Nagabodhi, his teacher Nagarjuna (again!) laughs at him when he sees Nagabodhi has produced horn on his head by the power of meditation. This laughter could be seen as mildly derisive or amused, or laughter of satisfaction, but not of exhilaration. In any case, it also occurs in the context of a story with *sandhabhasa* elements referring to the use of *Amanita muscaria*. I will return to a discussion of the story of Nagabodhi below, after the material on Karnaripa-Aryadeva.

> Having understood that realization had arisen in his student he said, 'Do not stay in samsara'. At the instant of hearing that, Karnaripa prepared to depart to the sky. There was a woman from among those mentioned before who paid her respects to the master and followed as attendant.
>
> The master said, 'What do you desire that makes you one who pays her respects to me?'
>
> The woman said, 'Because I do not need anything else at all, because I am a follower from attachment to your eye, I need your eye'.
>
> The master plucked out his right eye, gave it to her and thereby became known in all directions as Aryadeva, the One-eyed.

3.11. The single eye

One of the many descriptions and epithets of Soma that Wasson interpreted as derived from the characteristics of the *Amanita muscaria* was 'the Single Eye'. The mushroom, at one stage of development, looks something like a bloody human eye-ball plucked from the socket and thrown on the ground. Wasson (1968, p. 46) cited five different lines of the Rg Veda connecting Soma with the image of 'the Single Eye'.

Working with Ruck, Wasson (1986, pp. 60-67) explained both the myth of the 'Shade-foot' people (Gr. *Sciopedes*) or 'One-leg' people (Gr. *Monocoli*) (who were said to leap about on a single, powerful leg when not resting on their back in the shade of their single foot), and the myth of the *Cyclopes*, the one-eyed people, as legends derived from characteristics of the *Amanita muscaria*. The Vedic Aja Ekapad, 'Unborn Single-foot' referred to above reflects the same characteristics.

Nebesky-Wojkowitz (1956, p. 122) provides a list of several one-eyed, one-legged, one-winged deities who have 'a physical anomaly typical of many of the ancient Tibetan divinities'. Included is the goddess Ral-gcig-ma (Skt. Ekajati or Ekajata) who has but one foot, one breast, one tooth, one tuft of hair and one eye with which she surveys the past, the present and the future, i.e. 'the three times' (1956, p. 34). Also given for comparison (1956, p. 539) are the similar Siberian demons: Anakhai, a one-eyed demon of the Buriats; Arsari of the Chuvashes, who has only one hand, leg and eye; and the initiatory demon of the Yakut shamans who has only one arm, leg and eye.

According to Dowman (1985, p. 121), Ekajata is not documented as an indigenous Indian deity. Bharati (1975, p. 38) suggests that Ekajata was a Tibetan import or reimported to India, citing Bhattacharya's translation of the colophon of *Sadhanamala* no. 141, which describes an Ekajata sadhana: 'restored from Tibet by Arya Nagarjuna' (Bharati, 1975, p. 74). He is probably referring to the *Ral pa gcig ma'i sgrub thabs* by Nagajuna, which has such a colophon (*bsTan 'gyur*, Peking #4340, vol. 81, pp. 9-10). It would be interesting to discover why this single-eyed goddess/demon seems to be shared by Siberians and Tibetans, but not Indians.

According to the legends, Karnaripa had but one eye because he gave one away. Although the recipient of the eye varies in different sources (compared below), in each version Karnaripa just plucked out his own eye to give away. This event is not worked smoothly into the story lines - it just happens abruptly - and there is no elaboration of the reasons why his eye was needed.

On the historical level, these legends might be the folk-history generated to explain the attributed lack of an eye by both the *Mahasiddha* Aryadeva II and also by his predecessor Arydeva I. Material in a Chinese source (Nanjio, 1883, no. 1462), recorded by Kumarajiva in the 5th century before the time of Arydeva II, makes it clear that his predecessor also was described as having only one eye (Malalasekera, 1966, p. 111).

What could the didactic significance of this part of the story be? I asked a Tibetan lama informant what the meaning of the eye plucking could be. He said that Karnaripa was practising the *paramita* of giving or generosity. Thus, it must seem to one who must guess without the benefit of other clues from the symbol system of *Amanita muscaria* use in Siberian shamanic, Vedic, Buddhist and Germanic (see below) traditions.

'The Single Eye' is both an epithet of Soma and of Karnaripa, who is not merely connected with the mushroom; he shares the name of the mushroom, he is equated with the mushroom. The deeper meaning of his having the mushroom's name and the gift of his eye is, as yet, unknown to me.

In the *sMan dpyad yan lag brgyad pa 'i shying po 'i 'grel pa las sman gyi ruing gi rnam grangs*, translated and edited by Dash (1987, p. 353), there is listed an herbal medicine of unknown botanical identity called *somaksi*, 'eye of soma' (these translations are mine). Synonyms of this medicine are given as *maha gulma*, 'great cluster of trees' or 'great tumor' or possibly 'great myrobalan', or in Monier-Williams (1899, p. 795) *maha gulma* is given as 'the Soma plant'; also *maha gara*, 'great drink' or 'great poison'; also *candra taru*, 'moon tree' or 'bright tree' ('bright' is the meaning of the Proto-Indo-European birch word **bherH-g-o-*) (Friedrich, 1970, pp. 27-29); and *dvija priya*, given in Monier-Williams (1989, p. 506) as 'dear to a Brahman, Aryan, the soma plant'. This list of synonyms for the unidentified drug *somaksi* provides, at least, another connection between Soma and 'the Single Eye'.

Candranandana, who compiled this pharmacopoeia, was a Kashmiri scholar (Dash, 1987, p. viii) who belonged to a period prior to 1013 C.E. when Rin-chen-bzang-po translated his works into Tibetan. It is impossible to say how many, if any, of the Kashmiri or Tibetan physicians who read these references to the drug *somaksi* actually understood the meaning of its names and really knew what it was. If the lineage of this secret knowledge were broken, then the tradition would be passed down like a riddle that no one knew the answer to, like the story of *Siddha* Karnaripa.

> Aryadeva Karnaripa practised the instructions of Lama Nagarjuna so the stains of his mind were cleansed and his mental continuum was liberated. At the instant of merely hearing the words of his lama, he levitated to the height of seven palm trees into the sky. He taught the Dharma to many beings so their mental continuums were made completely mature.
>
> While the lama sat below him, he pointed his feet into the sky. By facing down, he folded his hands and bowed down to his lama. He levitated up into the sky and the gods above caused a rain of flowers. He disappeared into suchness.
>
> The End

3.12. Lustful women-sky journey-anointing

There was some imagery in Karnaripa's story that I examined with inconclusive results. I was curious about the 'lustful women' (*bud med chags*) who gave Karnaripa the 'delicious alms'. They may be related to the dryad or tree goddess of fertility (Skt. *vrksaka*) who appears as a voluptuous beauty, scantily clothed, embracing the tree tightly, amorously wrapping one leg around the tree trunk like a vine or *lata*, 'both 'creeper' or 'vine', and 'woman'' (Coomaraswamy, 1971, p. 32). Soma was referred to as a *lata* (Wasson, 1968, pp. 97, 98, 103 ft., 106-108, ll0, 123, 125). Also, in Sanskrit as in English, the term 'horny' relates the image of the horn '*srnga*' to the erotic sentiment '*srngara*' (Monier-Williams, 1899, p. 1087). I will discuss below the connection of the horn with the *Amanita muscaria*.

I was also curious about Karnaripa's aerobatic manoeuvres at the conclusion of his story. Such 'sky-going' is not unusual for Indian yogins, including tantric *siddhas*. It is also common behavior for shamans, including those of Siberian traditions. Karnaripa's ascension to the height of 'seven palm trees' is a close parallel to the Siberian shaman's journey through the seven heavens as he climbs up the seven notched steps in the birch pole representing the seven-branched World Tree (Eliade, 1964, pp. 264, 270-279). 'Ostyak and Lapp shamans eat mushrooms with seven spots to enter into trance; the Lapp shaman is given a mushroom with seven spots by his master' (1964, p. 278). I intend to do further research comparing Buddhist tantric celestial journeys with shamanic celestial journeys with special attention to numerical or arboreal references.

Finally, I wondered about the 'dead tree' on which Karnaripa 'smeared' or 'anointed' (Tib. *byugs*, Das, 1902, p. 924) the alchemical medicine. I think the dead tree could be the neurological network that has not experienced revitalization and realization, by one means or another. The use of the specific verb '*byug*' instead of a more common, general verb like 'put' (Tib. *rgyab*) could be significant. According to Allegro (1970, p. 56) the slimy, slippery mushroom thrusting up through the earth was seen as the erect penis of the Father God which had been anointed or 'christened' with semen and sexual fluids, becoming 'Christos' the Anointed One. For a Sanskrit synonym, Monier-Williams (1899, p. 11) gives '*anji*,... ointment... unctuous, smooth, sleek (*membrum* *virile*)'. Another Sanskrit synonym for 'smear, anoint', *lip* (1899, p. 902) gives us *limpata*, 'libidinous, lustful' (1899, p. 902), possibly meaning 'anointed with perfumed oils'. According to Tucker (1931, p. 13), the original ambrosia was neither food nor drink of the gods. It was 'unguent' of the gods, body fluids which worshippers smeared onto the fetish-stone (Gr. *baetulos*) (Tucker, 1931, p. 34). Allegro (1970, pp. 265-66) suggested a derivation of *betula*, 'birch', from *baetulos*. The role of 'Anointing' in the earliest religions needs research.

4. Results of the interpretation of the secret meaning

I am sure that a number of apparent connections I have suggested between the images in the story of Aryadeva and the *Amanita muscaria* may be coincidental and meaningless overlappings of symbols and epithets. A few of these meaningless coincidences are probable. However, a set of such coincidences would be improbable. The congruity of the set of symbols in the legend of Arydeva and the sets of symbols in the mythology of *Amanita muscaria* from Siberian and Vedic traditions is too strong to be a coincidence. It seems that there is enough evidence to conclude that the alchemical elixir of these *siddhas* contained the psychedelic mushroom *Amanita muscaria*: the references to a potion which provides both wisdom and magically potent urine, the references to the Single Eye, the references to the partial appearance of the goddess from the tree. These references must refer to the *Amanita muscaria*, as they do in other traditions.

The other references to the 'miraculous birth', to the 'delicious alms', to the 'wheat cake on the tip of a needle', to the 'rice pulp' *somam*, to the 'God of the Aryans', to the 'full vessel', probably refer to the mushroom, especially when considered in addition to the first set of definite references. The meaning of the secret language is obvious if one has guessed the secret.

Not so obvious is the information at the historical and didactic levels of the *sandhabhasa*. In these areas the legend presents many more questions than answers: what is the exact connection between the psychedelic mushroom and the historical (?) persons Aryadeva (2nd cent.) and Karnaripa (8th cent.)? Why do they have an epithet of the mushroom as their proper names? What is the connection of the mushroom to the two Nagarjunas? If this alchemical practice really existed, what was its source and its lineage of transmission? How long did the tradition remain unbroken? When was the last time the story of Karnaripa was read by someone who understood its secrets? What, if any, is the connection of the mushroom with the *Guhyasamaja* tantra into which Karnaripa was initiated by Nagarjuna? In the legend, the realization through alchemy seemed to be completely unrelated to the tantra.

And in regard to considerations of didactic content: Who should attempt to attain this alchemical *siddhi*? And who should not? What is the nature of the practice and process? What results should one expect? What are the signs of development and attainment? What does one need to know to practice this alchemy and where can one learn this? What is the meaning of the gift of the eye? In Karnaripa's story there is some obvious didactic intent in the *sandhabhasa* and I present my interpretation here.

At the beginning of the legend, Karnaripa is described simply as the principal of one hundred thousand monks at Nalanda college. His high degree of intellectual attainment and the instructions he received from many masters were not sufficient for him to experience realization. When Manjusri, the God of Wisdom, appeared to him as a lowly fisherman, Karnaripa's undefiled vision allowed him to see through the god's appearance and recognize him. This same undefiled vision allowed Karnaripa to see the tree goddess in her true form, although he did not realize the true nature of her gifts of alms, i.e. the potential value of the psychedelic mushroom. In contrast we have Nagarjuna who recognized her alms as the essential alchemical elixir, but could not see the true form of the tree goddess.

The meaning of this seems to be that, to obtain the *siddhi*, one needs both to have entirely abandoned one's defilements (evidenced by Karnaripa's miraculous birth, scholastic attainments and his instant recognition of Manjusri and the tree goddess) and also to have knowledge of the identity and the potential virtues of the alchemical elixir (evidenced by Nagarjuna's recognition of the gifts of alms, and his knowledge of its manner of preparation, consumption and of its effects). This interpretation seems to conform smoothly to Karnaripa's spiritual development in the story, but an evaluation of Nagarjuna's role presents some questions.

Is his recognition of the signs of attainment due to his personal experience or to teachings he had received?

How has his failure to abandon entirely his defilements affected his ability to obtain this *siddhi*? How has he deserved the title of 'Master' while retaining these defilements? The substance of the dialogue between Karnaripa and Nagarjuna on questions like these would be most interesting to read; however, we have only their simple conclusion: 'We need to eat the alchemical medicine'.

By testing the magic power of Karnaripa's urine after they drink the elixir Nagarjuna determines that realization has arisen in his student. He knows that Karnaripa, through the intuitive insight he has experienced, needs only to hear his teacher's words in order to leave *samsara* behind.

The legend adds that Karnaripa then practised the instructions of his teacher so that the stains of his mind became pure and his mental continuum was liberated, this happening after he had already entirely abandoned his defilements and after realization had arisen. These may be references to different, specific stages of attainment. Karnaripa's further practice of his teacher's instruction and the rest of the story might be an addition to the original legend added by the compiler in his stylistic homogenization of the conclusions of the legends.

4.1. Aryadeva's legend by Bu-ston and Taranatha

Two other sources of 'biographical' material on Aryadeva and Nagarjuna are the works of Bu-ston (14th century) and Taranatha (1608). I made my own translations of some of this material which I will summarize and analyze.

Bu-ston's account of 'the teacher Aryadeva' begins with his miraculous birth from a lotus flower in Simhala (Sri Lanka) where he was adopted by the king. When he grew up he became a student of Nagarjuna and became learned in all branches of science and all Buddhist and non-Buddhist philosophical systems.

After this brief introduction, Bu-ston seems to begin to focus on the main event in his account, Aryadeva's defeat of the heretic. A non-Buddhist (Sivaite) teacher named Matrceta, who had done much damage to the Dharma, came to Nalanda to contest the Buddhists there. They sent a message to summon Nagarjuna, but Aryadeva came instead to convert Matrceta. This seems to set the stage for the great contest, but that event is barely mentioned in the rest of the story, which I translate unabridged:

> When Aryadeva was coming, a tree goddess begged for one of his eyes, and he gave her one eye. Then, when he had defeated the heretic, it was said, 'This one-eyed one, what sort is he?' [Aryadeva] said,
>
> > 'Siva has three eyes yet he cannot see reality. Indra has one thousand eyes but he cannot see reality. Aryadeva has only one eye; whatever he is, He sees the reality of all the three worlds',
>
> (Bu-ston, 1971, f. 834, I. 3-5)

It is added that Matrceta converted to Buddhism and became a great *pandit*.

Bu-ston then gives a list of the works written by Aryadeva, drawing no distinction between Aryadevas I and II.

Again, it is uncertain whether the attribute of miraculous birth in Bu-ston's retelling was intended by the original composer of that element of the legend to be taken as a hagiographic detail or more specifically as a *sandhabhasa* reference to the *Amanita muscaria*.

Bu-ston has Aryadeva giving his eye to a tree goddess. It is uncertain whether this detail of the story, i.e. the tree goddess, originated in the legend of the second century Aryadeva or the eighth century Aryadeva. It may be impossible to decide which symbols referring to the mushroom were contributed to the conflated legend in reference to Aryadeva I or Aryadeva II, or which symbols were originally and intentionally shared by both legends.

The Single Eye was shared by both Aryadevas. A Chinese source (Nanjio, 1883, no. 1462) explains Aryadeva's epithet of Kanadeva, 'One-eyed God' saying he gave his eye to Mahesvara, after the previous day plucking an eye from a golden statue of the god (Malalasekera, 1966, p. 111). This reference proceeded the time of Araydeva II who was also famous as Karnaripa, Mig-gcig-pa, 'the Oneeyed'. Even if this symbol in the conflated biography belongs only to the legend of Aryadeva I, then other symbols suffice to link Aryadeva II as well to the *Amanita muscaria*.

Bu-ston's short account does manage to include three images from the *Amanita* symbol set: the miraculous birth, the gift of the single eye, and the tree goddess. He also provides us with Aryadeva's own answer (he writes) to the question, 'Who or what is this one-eyed Aryadeva?' The actual interrogative in the Tibetan text is not simply 'who'(*su*) or 'what' (*ci*) but *ci'dra* meaning 'like what?' or 'what sort?' (Das, 1902, p. 695).

Aryadeva's reply is both informative and evasive. He says that, whatever he may be, his single eye sees all of reality, the reality unglimpsed by the three eyes of Siva or the thousand eyes of Indra. He seems to be saying that his own identity is unimportant, except for his Single Eye of omniscient vision. If my interpretation of this *sandhabhasa* is correct, Aryadeva says that the vision provided by the psychedelic mushroom is far superior to the vision of the supreme deities of heretical religions (he did not compare himself with the Buddha).

I have the feeling that many scholars of Buddhism will find it easier to believe in psychedelic drug use by the Tantric Aryadeva and Nagarjuna than by their Madhyamika predecessors. It must be remembered, though, that besides being the founders of the Madhyamika tradition, both Nagarjuna I and Aryadeva I were credited with being masters of all branches of science and all forms of orthodox and heterodox philosophical systems which should have included alchemy.

Taranatha's account of Aryadeva begins with a discussion of the circumstances of his birth, relating the royalty of his birth as verified by other sources, but discounting the miraculous form of the birth, which he seems to attribute to the Tibetan people's fondness for rumours. He continues with a short history of Aryadeva's spiritual career, mentioning Nagarjuna's initiation of Aryadeva into alchemy. Then comes the main event of the legend, the debate with Matrceta. The monks of Nalanda wrote a letter to summon Aryadeva to the debate and tied it to the neck of a raven (*bya rog*, also 'crow', both birds sharing synonyms in Tibetan and Sanskrit) which had come out from the heart of a self-arisen stone image of Mahakala.

Although the raven or crow has not yet been recognized as an element of the *Amanita* symbol system, I could not dismiss that possibility without further investigation.

The first connection I have found between the raven and the *Amanita muscaria* is in some Siberian (Koryak) folk tales (Wasson, 1968, pp. 294-301) in which the hero 'Raven-man' shows his love for eating fly agaric. Another Koryak story (Wasson, 1968, p. 268) connects the hero 'Big Raven' with the origin of the fly agaric. Big Raven was unable to lift the provision bag of a whale to help it escape when it had run aground. The Supreme Being spat on the ground and the fly agaric appeared there from his saliva. Big Raven ate the mushrooms, began to feel gay, to dance and he helped the whale escape. Fly-agaric showed him how the whale returned to his comrades, so Big Raven said, 'Let the *wa'paq* [*Amanita muscaria*] remain on earth, and let my children see what it will show them'.

Another connection of the raven and the fly agaric comes from the Hindu Kush in the extreme north-east region of Afghanistan. In regard to modern use of the mushroom there, Wasson (1982, p. 601) cited an article from the *Afghanistan Journal* 6 [2], 1979 in which three old mountain-men referred to their fly agaric as 'raven's bread'. This epithet, apparently unexplained in the article, received no further attention from Wasson.

Again we find possible connections between the crow and the fly agaric in Monier-Williams (1899) where we find these entries: under *kana*, 'one-eyed... *kanas*, a crow' (p. 269); *ekaksha* [*eka* 'one' *akshi* 'eye'], 'one-eyed... *ekakshas*, a crow' (p. 267). It is added that crows are supposed to only have one eye which they move from one side to the other as required.

Also given under *drona*, 'a wooden vessel, bucket,...; a Soma vessel; a raven or crow; *dronakaka* a raven' (Monier-Williams, 1899, p. 503). It is uncertain if this reference connects the raven specifically to the Soma bucket or merely to any kind of bucket.

Unless these examples are coincidences, it seems there has been some relationship between the raven/crow and the fly agaric across much space and time. As for the details of this relationship, I have none. The raven, a carrion feeder with color vision, would have noticed the bright-red *Amanita* long ago and it would be known by now if they enjoyed their 'raven's bread'.

According to Taranatha, after he received the message tied to the raven, Aryadeva went to Nalanda with the aid of the object of swift transport (*rkang mgyogs kyi rdzas*). On the way, he met a woman of a non-Buddhist sect who needed the eye of a learned *bhiksu* as a ritual implement to attain her siddhi; so he gave her one of his eyes.

'There he subdued the allies of the heretic [Matrceta] - the sister *pandita*, the parrot, and the chalk - by means of a shameless monk, a cat and a jar of black oil' (my trans.) (Taranatha, n.d., p. 81). Some details of this tantric contest are added in a version from oral tradition given by Geshe Wangyal (1973, pp. 49-50) in which Mahesvara aided Matrceta in the debate by entering his body and empowering him to shoot all-destroying flames from his forehead. Sarasvati (in place of the 'sister *pandita*') aided him with beautiful and wise phrases. A *pandit* in the form of the parrot would whisper advice in his ear. Siva wrote advice in the sky with the chalk (another version has the writing on a chalk board). Aryadeva countered by bringing a naked man (in place of the shameless monk) which caused Sarasvati to turn away, a cat which jumped up and killed the parrot, and by spreading vanishing oil in the sky (or on the chalk board) to erase the writing. He also brought a dirty boot which drove away Mahesvara.

As Taranatha continues, Aryadeva defeated Matrceta three times and caught him when he tried to escape by flying away. Matrceta was later converted to Buddhism.

I could find no connection between the fly agaric and the allies of Matrceta, nor to the jar of black oil. Aided by Sanskrit glosses offered by Lama Chimpa (1970, p. 125) I immediately came upon two Sanskrit-Tibetan puns which connect the mushroom with the shameless monk and the cat.

In the Tibetan text, the *dge bsnyen* (Skt. *upasaka*, 'Buddhist lay worshipper') is described as *spyi brtol can*, given in Das (1902, p. 807) as 'impudent, shameless, daring' or 'scurrilous, foulmouthed' deriving from *gtol*, 'to disclose' or *rdol* 'to come out' and *spyi* 'general, public'. Lama Chimpa offered as Sanskrit synonyms *kakola*, probably drawing on *Mahavyutpatti* #4863, '*spyi rtol, kakola*', which is given in Monier-Williams (1899, p. 268) as a 'raven'. Evidently the 'wild, wary and suspicious Tibet Raven becomes bold when scavenging around villages...' (Wilmore, 1979, p. 156). This characteristic provides a pun which invokes the shameless/raven/Single eye/*Amanita muscaria* symbol set.

Aryadeva's cat, Tib. *byi la*, is another point in the same equation. Sanskrit synonyms are *vidala* (Das, 1902, p. 888) and the same by Lama Chimpa, found in Monier-Williams (1899, p. 731) under bidala (= *vidala*) as 'a cat .... the eyeball'. This invokes the cat/Single eye/*Amanita muscaria* symbol set.

4.2. The siddha Nagabodhi

Taranatha follows his story of Aryadeva with those of three other disciples of Nagarjuna: Nagavyaha, Nagabodhi and Shingkhipa, all receiving shorter entries than Aryadeva. It is mentioned that Nagabodhi attained the *siddhi* of alchemy (*bcud len gyi dngos grub*).

The story of Nagabodhi given by Abhayadatta (Robinson, 1979, pp. 233-235) does not mention alchemy (openly). In his version, the story opens with Nagabodhi, a thief, looking through a door at Nagarjuna who is eating delicious food from a golden bowl.

I see the reference to this meal as a possible expression of the 'delicious food'/ambrosia/soma/*Amanita* set. Although I am unaware of a precedent, the 'golden bowl' would be a good description of the partially opened mushroom cap, which can vary in color from deep red to light yellow through all shades of golden-orange.

Nagarjuna, reading in Nagabodhi's mind his intention to steal, throws the bowl of food out of the room at him, saying objects of desire, like all things, are transitory phantoms of the mind, able to be produced and destroyed by mental concentration. He instructs Nagabodhi to create, in place of his desires, horns on his head, and by meditating he does so. Realizing the emptiness of all things, he attains *siddhi*.

In Taranatha's version, elements of this story of Nagabodhi appear in the story of the *mahasiddha* Shingkhipa, who is described as 'dull witted' (*blo rtul ba*), so dull witted he could not memorize even one verse after many days. Nagarjuna instructed him to create horns on his head by meditating and later, to remove the horns by meditating. After instruction in the Stages of Completion, Shingkhipa attained the *Mahamudra siddhi*. Although it did not seem a likelihood to me, I investigated the possibility that the image of a horn, or horns, was an expression of *Amanita* symbolism.

Wendy Doniger O'Flaherty (1981, p. 263) refers to 'the sharp-horned bull' as 'a common metaphor for Soma'. Here, emphasis seems to be placed on the horns. Furthermore, in Monier-Williams (1976, p. 51) as a synonym for 'birch' we find *srngi*, and under *srngaka* we find (Monier-Williams, 1899, p. 1008) 'a kind of Betula or birch tree'. What is this connection between birch trees and horns (Skt. *srnga*)? It has been pointed out (Lama Chimpa, 1970, p. 127) that the name Shingkhipa is certainly derived from *srngin*, attested by its Tibetan translation *rwa can* 'the horned one'.

In Dowman's version (1985, p. 350) the horns produced by Nagabodhi are red horns; no reason is given for this coloration which matches the fly agaric. These red horns may link Nagabodhi/Shingkhipa to the birch tree and to the *Amanita muscaria*. An even weaker clue was the 'delicious food' in the 'golden bowl' on which Nagarjuna dined. I would not even mention these as possible mushroom references, except that they are followed by an almost certain reference to the *Amanita muscaria* in an otherwise enigmatic addendum to the story of Shingkhipa by Taranatha. Here is my translation:

> Then the master, together with his retinue, practised mercurial alchemy for 6 months. After success was attained, when the pills were being dispensed to each of the disciples, he [Shingkhipa] touched his head to the pill, put it down and turned away. So when the master asked the reason, he said, 'I have no need of this. If the master himself wishes something like this, prepare vessels filled with water'.

Accordingly, one thousand great wine vessels were filled and the forest appeared filled with them. He poured a drop of his urine into each of the jars so that all of them became the resultant nectar, the transmutative juice. Master Nagarjuna hid all of them in an inaccessible cave of one side of that mountain. He offered a prayer to benefit all future sentient beings. This dull witted one who attained *siddhi* was called Shingkhipa, 'the horned one'. (Taranatha, n.d., p. 83)

This reference, which equates the magically potent urine of the *siddha* with the alchemical elixir, may be taken as a reference to the use of *Amanita muscaria* for reasons explained above in connection with Aryadeva. Again, the didactic content of the story is not so obvious. It is uncertain how much of that information was intentionally obscure, and how much detail has been lost due to the entropic process of oral tradition. There seems to be a parable regarding fly agaric use in the story of the Horned-one, but my analysis of the story gives more questions than answers.

If the golden bowl of delicious food is a mushroom reference, then Nagarjuna appears to be telling Nagabodhi that he does not need this material, he only needs the power of meditation. If the horns on the head are a mushroom reference, when he advises his disciple to create them, is Nagarjuna advising the use of mushrooms or the use of meditation in place of mushrooms? His potent urine is proof that the Horned-one had consumed the fly agaric. When Shingkhipa does not accept his masters gift of the magic pills of mercurial alchemy and offers, in return, his magic urine, is he saying that he doesn't need it because he can now dispense it, or that mushroom alchemy is superior to mercurial alchemy, or that meditation can create potent urine?

Although I have tried to find other examples of such magic urine in Buddhist literature, the only two examples I now have are in Abhayadatta's story of Karnaripa and Taranatha's story of the Horned-one, both students of Nagarjuna II.

4.3. Sakara and Padmasambhava

I have mentioned above two others of the eighty-four *siddhas* who are described as lotusborn. The *siddha* Pankaja was also born of a lotus blossom and was also a disciple of Nagarjuna II, but his legend has no obvious symbols in common with the mushroom traditions. The 'real' identities of the *siddhas* Pankaja and Sakara are even more complicated to determine than the identities of the Aryadevas and Nagarjunas. These matters are discussed by Dowman (1985, p. 266 and pp. 344-346). I will limit my discussion to the similarities of the stories of Sakara by Abhayadatta (Robinson, 1979, pp. 227-230, ft. 276-283, pp. 380-382) and of Padmasambhava (Evans-Wentz, 1954).

According to the legends, both individuals were born to heirless kings who had prayed for sons; both were born in lotus blossoms after their births were foretold in dreams; both abdicated to seek the Dharma. In the remainder of the story of Sakara, aside from a reference to rice pulp ('*bras chan*, *somam*?), I have found no symbolic references to the mushroom but some familiar images appear in the legend of Padmasambhava.

To end the famine in his land, King Indrabhuti, who was blind, descended to the world of the *nagas*, to obtain from them the wish-granting gem. When it was given to him by the princess of the *nagas*, he wished for sight in one of his eyes and it was granted. When he returned to his kingdom he found the miraculously born Padmasambhava seated in a giant lotus blossum, 'a fair, rosy-checked little boy' encircled by an aura, his face beaded with perspiration. Upon hearing Padmasambhava's first words, the king was no longer blind in his other eye (Evans-Wentz, 1954, pp. 105-109).

Later in the story, Padmasambhava was sent into exile and the king gave him the wish-granting gem, but Padmasambhava returned it saying, 'Whatever I behold is my wish-granting gem'. When the king extended his open hand to receive it, Padmasambhava spat in the king's hand and the spittle instantly became another wish-granting gem (Evans-Wentz, 1954, pp. 117-118). Here we have two 'Single eye' stories united, one eye cured by the wish-granting gem and the other eye cured by the words of Padmasambhava.

In Taranatha's story, the Horned-one returned the alchemical pills to Nagarjuna and offered his urine as the equivalent. In this story, Padmasambhava returned the wish-granting gem to the king and offered his spittle as the equivalent. The possible connection of the psychedelic mushroom with the wish-granting gem is worthy of further examination. Recall the Koryak tale cited above regarding the origin of *Amanita muscaria* from the spittle of the Supreme Being. I will give below another example of spittle which produces *Amanita muscaria*.

The birth of Aryadeva is also mentioned in the legend of Padmasambhava (Evans-Wentz, 1954, p. 156), who was said to be present when Aryadeva appeared in a lotus blossom as a beautiful eightyear-old child with a perspiring face. I am not sure if this detail of a face beaded with perspiration is an intentional reference to the mushroom or a reference to something else added by a later redactor. Possible referents of the beads of perspiration on the face are the white spots of the universal veil on the red ('rosy-checked') mushroom cap, or the strong diaphoretic quality of the mushroom.

Once again, in these legends of lotus-born ones, we are given symbols which seem to be commonly held with the fly agaric symbol set, but the deeper didactic content of these symbols is unclear. This opacity maybe the result of missing, misemphasized or rearranged details due to transmission of the legends by uninformed non-practitioners, as in the interpretation of the story of Karnaripa by Dowman and his lama informants. Once the informed lineage was broken, those who passed down the legends of these Buddhist adepts could not correct erroneous variances, lacking practical knowledge of the real meaning of these legends.

4.4. Aryadeva and Odin

In what at first must seem like a whopping non-sequitur, I will compare the Tibetan legends of these Buddhists with the legend of the chief god of the Germanic pantheon, Odin.

In the prose introduction to the Eddic *Lay of Grimnir* (also in the *Gylfanning* of Snorri Sturluson), Odin is described as sitting in his high seat in Asgard, from where, with his single eye of omniscient vision, he can see everything that happens in all the three worlds of the Germanic universe. I think it is no mere coincidence that this description of Odin is the same as Aryadeva's selfdescription in Taranatha. Among Odin's many names and attributes are Har and Bileyg, both 'the One-Eyed'. Odin had but one eye because he traded his other eye to Mimir, the owner of the well of wisdom and understanding beneath the tree Mimameith, 'Mimir's tree', often taken to be Askr Yggdrasils, 'Ash of Odin's Steed', the World Tree.

Mimir was the wisest of the Aesir, the race of gods to which Odin and Thor belong, because he drank every day from his well of wisdom. He drank from the Gjallarhorn until Odin, in order to receive a single drink from the well, pledged one of his eyes in return. After that, Mimir drank each day from 'Odin's pledge'. This imagery has perplexed scholars of Eddic mythology who were unaware of the 'kenning' of *Amanita muscaria* as the Single Eye in other traditions.

Mimir was taken hostage by the Aesirs' foes, the Vanir, who cut off his head. Odin smeared it with wort to preserve it and it could speak words of wisdom in answer to his questions. In the *Sigrdrifumal* v. 14-15, the Valkyrie Sigrdrifa speaks of 'mind runes' which Hropt (Odin) devised from the 'sap which seeped in drops out of Heithdraupnir's head, out of Hoddrofnir's horn', evidently referring to Mimir's head and horn (trans. by Hollander, 1962, p. 236 (who points out an intriguing lacuna in these verses)). 'Mimir' apparently means 'the Thinking One'. What is this sap which drips from his head or his horn to form 'mind runes'?

Another of Odin's names is Hrafna (Raven)-god. This name has been believed to relate his role as War god to the ravens that haunt battlefields feasting on the dead. It might also reflect the role of Odin as Great Seer. Odin had two ravens Hugin and Munin, 'Thought' and 'Remembrance', which flew over the world, telling him all they saw. I am unaware of any connection of the raven and the Single Eye in Germanic mythology, but Odin's two ravens might be his own two eyes sent forth in shamanic vision quest.

Odin gives a long list of some of his names and attributes in the *Grimnismal*, of which many could possibly be seen as expressions of *Amanita muscaria* symbolism, for instance, Odin's name Sithhott, 'Long-Hood' (Hollander, 1962, p. 63) or Sidhhottr, 'With Broad Hat' (MacCulloch, 1930, p. 43). Other than 'Bileyg', it is likely that most of these names refer to something other than the mushroom, although Odin's characteristic broadrimmed hat is worthy of further consideration.

We have then, in the myth of Odin, at least six symbols which also appear in the fly agaric symbol systems of other traditions: the Single Eye, the sacred tree, the deity beneath the tree, the well of wisdom beneath the tree, the elixir of wisdom, and the raven. Odin also bears a name of the mushroom as one of his own names, as does Aryadeva/Karnaripa: One-Eyed. If my interpretation is correct, then the legend says that Odin, the Oldest God, attained his omniscient vision by consuming *Amanita muscaria*.

As in the Buddhist legends, it is very difficult to determine exactly how, when, why or where this connection to the mushroom became part of Odin's legend. I intend to follow up with further research in this area.

4.5. The Celtic version

One variation in this tradition is that the World Tree of the Germanic universe is not the birch, but the ash (*Fraxinus* sp., or more likely *Sorbus aucuparica*) which is not a symbiont of the *Amanita muscaria*. In the Celtic myths, the sacred tree is the rowan or quicken tree, the mountain ash, *Sorbus aucuparica*, not a true ash but so named for its many ash-like physical characteristics.

Unlike the true ash which bears samaras, the rowan bears as fruit small red pomes or rowanberries. These were considered to be the ambrosia of the gods which cured all diseases, and brought exhilaration and rejuvenation. These red berries appear in one episode in the legend of the Pursuit of Diarmait O'Duibhne and Grainne.

The Tuatha De Danann, gods of the Gaels, brought these berries from the Land of Promise, but when one fell to earth, from it grew the rowan tree. When the gods found that they had carelessly endowed mortals with their ambrosial berries, they sent a savage one-eyed giant, Searbhan (Sharvan) the Surly, to kill any mortals who tried to eat the berries. This one-eyed giant was later killed by Diarmait when Grainne wished for some of the berries. Then they hid in the dead giant's hut in the tree until their pursuers found them and they fled again.

Several of the *Amanita muscaria* symbols appear in this legend, but in an altered form. In this case, the ambrosial food is a red pome, the Cosmic Birch Tree is a Celestial Ash Tree, and the Oneeyed God who attains wisdom is a Surly, One-eyed Giant who kills wisdom seekers. I don't know if these alterations are intentional didactic changes in the Ur-legend of the mushroom, or whether they are unintentional degenerations due to retelling of the legend after the knowledge of its true meaning was lost.

Although the ambrosial rowanberries were so strongly desired by Grainne, the story never mentions her eating them, nor any change in her due to possession of the berries. This would have been an important element to include in any legend intended to teach the real importance of the psychedelic 'berries'. In the legend of Finn mac Coul there are nine magic hazel trees which bore crimson nuts that gave universal wisdom to anyone who ate them. They fell off the trees into a well below, where lived the divine 'Salmons of Knowledge', the only class of creatures privileged to eat the crimson nuts. Finn attained knowledge by eating one of the salmon.

Although the shift of sacred tree in Celtic myth from birch to ash was not accompanied by a linguistic shift, the linguistic shift occurs in Italic (Latin) where the cognate of **bherH-g-o-* (birch) is *fraxinus*, which names the ash. Of all the western stocks of Indo-European, only Celtic lacks a birch cognate (Friedrich, 1970, p. 173). The Latin name of the mountain ash was *Sorbus*, possibly derived from Proto-Indo-European **sor-dho-s* which referred to some bush or tree that bore red or black berries (Friedrich, 1970, p. 150). The Latin name of the birch was *betula*, a word of unknown derivation, possibly coming from Celtic (Tucker, 1931, p. 34). When the names and the meanings of the names of the sacred trees of these traditions have been sorted out accurately, the history of the religious use of fly agaric will be easier to trace.

In a rare 'non-finding' of fly agaric in a tradition in which they were said to appear, Wasson (1968, pp. 177-178) denied that the *Amanita muscaria* was in any way connected to the Viking berserkers, who were believed to eat the mushroom to 'go berserk' in a murderous frenzy. I do not wish to argue that the berserkers did eat the mushroom, but I will point out that there is evidence against both of Wasson's reasons for his denial. His second reason was that the 'symptoms of fly agaric intoxication were the opposite of berserk-raging' (Wasson, 1968, p. 178). Although I have a longer argument that is beyond the scope of this paper, I will say that evidence against this point exists in the pages of *Soma* (Wasson, 1968) in several anecdotal descriptions of the mushroom's effects.

Wasson's first reason for his denial was that 'fly agaric is never mentioned in the Sagas or Eddas'. I am sure that if someone had used a similar argument against his identification of Soma, he would have considered the argument ludicrous. He certainly knew that, to find a reference to *Amanita muscaria* use, one should not look under 'fly agaric', nor even 'mushroom' in an index to the Eddas; one should start by looking for imagery that is known to appear elsewhere in reference to the mushroom, for instance the one-eyed demons of the Siberian tribes, the Single Eye Soma of the Aryans, or the Kanadeva/Mig-gcig-pa of the Buddhists. Even if Wasson had not been looking specifically for this imagery, he could not have read the story of Odin's single eye without recognizing it. Furthermore, this attribute of Odin is certainly not arcane. One cannot read the Eddas, nor even the most general account of Norse mythology, without finding a description of Odin and his single eye.

How could Wasson have made such a glaring, uncharacteristic oversight? The only answer I can conceive of is that he did not want to find any evidence that could connect his wonderful, noble, 'entheogenic' mushroom with the war party drug-of-choice of those Hell's Angels in longships.

The berserker question is certainly an insignificant sidebar to the possible connections of the fly agaric with Odin. My suggestion that such evidence exists is not without precedent. Morgan (1986, p. 45) in some references linking Santa Claus to the fly agaric reports a belief of the people in Kocevja in southern (former) Yugoslavia, that on Christmas night, Wotan the king of the gods rides through the woods on a white horse, pursued by devils. Wherever the red-and-white flecks of foam from the horse's mouth fall to the ground, they grow into next year's crop of fly agaric. Besides linking the *Amanita muscaria* to Odin and to Santa Claus, this legend is the third example I have given linking the origin of fly agaric to spittle (see also Allegro, 1970, p. 56).

The theory linking Santa Claus to the *Amanita muscaria* has been attributed to Ott (1976, p. 97) wherein he credits (n. 146, p. 154) 'Roderick, B. personal comm.'. Santa is seen as a Siberian shaman ('lives at the North Pole') who performs a winter solstice (Christmas) ritual. In typical shamanic behavior, he flies through the sky (with his reindeer, which are known to be very fond of fly agaric). He enters and leaves the yurt through the smokehole at the top ('up the chimney he rose') (Eliade, 1964, p. 262), climbing down and up the birch pole (Christmas tree) which supports the roof. The colors of the mushroom are red and fuzzy white, as is Santa's costume. If Santa Claus had but one eye, or if magic urine had been a part of his legend, his connection to the *Amanita muscaria* would be much easier to believe.

5. Conclusions

In suggesting the connections between the symbols in these legends and the *Amanita muscaria*, it is certainly not my intention to pound a square peg into a round hole. If any of my suggested interpretations can be shown to be incorrect, this will trim the deadwood, and my case will stand on the points that remain. I hope the few loose ends left above will not detract from the fabric of my argument regarding Abhayadatta's legend of Karnaripa. I hope my efforts to examine every possible clue will not be mistaken for Wassonian 'monomaniacal... paranoid.., mycocentricity' (Weil, 1988, pp. 489-490).

The suggestion that some Buddhist *siddhas* used a psychedelic drug will be dismissed out of hand by many. The use of 'intoxicants' is against the contemporary orthodox Buddhist ethic. In a footnote to his interpretation of a beer-brewing recipe as a metaphor for the process of enlightenment, Ardussi (1977, n. 37, pp. 123-124) denies 'that Vasubandhu's reference to magical powers deriving from the use of herbs (*Abhidharmakosa* VII. 53) suggests a type of mystical experience comparable to, or contributing to the better understanding of experiences obtained otherwise through meditation'. I believe I have demonstrated that some contemporary nonorthodox Buddhist 'alchemists' find precedents in the *Mahasiddhas* Nagarjuna and Aryadeva, who agreed, 'We need to eat the alchemical medicine'.

Perhaps my analysis of these legends and symbols can provide a basis for new research by scholars of Buddhism, Tantra, alchemy, Soma studies, Eddic studies, ethnopharmacology, comparative mythology, transpersonal psychology, shamanism and history of religion.

The relationship of a drug-induced psychedelic experience to 'genuine' mystical experience or to Buddhist enlightenment is debated today (Ratsch, 1989; Tart, 1991) as earnestly and as inconclusively as it was in the early years of wide-spread use of psychedelic drugs. I believe my identification of *Amanita muscaria* as the alchemical agent which brought 'realization' to these Buddhist adepts can help determine the value of the psychedelic experience in Buddhist tradition. Orthodox scholars may object but they can no longer 'Just say No'.

For my line of research into the Germanic myths I am indebted to my good friend Birrell Walsh, who informed me of Odin's monocularity when he heard I had an eye out for that kind of imagery.

Abstract

Hypotheses advanced in *The Road to Eleusis*[1] concerning the possible composition and method of preparation of the kykeon are evaluated in light of published criticism. Objections to the *Eleusis* theory are countered, and based on a largely overlooked aspect of the chemical hydrolysis of ergot alkaloids, a new hypothesis is suggested that reinvigorates the *Eleusis* debate. In part 2 of this essay, organic chemist Daniel M. Perrine provides further considerations that build upon the new idea, and a technical discussion of the practicality and realisability of the "Ergine Hypothesis" paves the way for new chemical and psychopharmacological research. In part 3, co-author of *The Road to Eleusis* Carl A. P. Ruck re-examines the Eleusis mythologies and ritual practises from which appear a much expanded understanding of the entheo-pharmacology of the ancient world.

Part 1

Introduction

In *The Road to Eleusis*, R. Gordon Wasson, Albert Hofmann and Carl A. P. Ruck attempted to resolve a long-standing debate concerning the famous Eleusinian Mysteries of ancient Greece. Earlier suggestions attributed variously to Karl Kerényi, R. G. Wasson, or Robert Graves had proposed that the autumnal phase of the rite might have involved the use of a psychoactive drug, and it was the task of *The Road to Eleusis* to propose a testable theory as to the nature of the *kykeon*, the revered sacramental potion that would have been a likely vehicle for such a substance.

The principal hypothesis proposed by the three authors suggests that the ergot species *Claviceps purpurea*, collected by the hierophantic priests from its natural and common parasitisation of barley growing in the Rarian plain adjacent to Eleusis, was the probable source of psychoactive ingredient for the elixir. *C. purpurea* and related parasitic fungi produce lysergic acid alkaloids, among which are several known psychedelic compounds as well as other important pharmaceuticals.

The partaking of the *kykeon* marked the climax of the famous autumnal ceremony at Eleusis, performed for nearly two thousand consecutive years and whose initiates included essentially all the great names of Greek antiquity. Claims for the potency and revelatory effect of the *kykeon* and the profound nature of the secrets revealed at the Eleusinian celebration are widespread in Greek literature and historical writings, so there can be little doubt that the rite was of major importance to the course of Greek civilisation or that the potion must have been more than a symbolic sacrament like the Christian Eucharist of bread and wine: the *kykeon* surely contained a powerful psychoactive substance similar to one of the major vision-inducing and psychedelic plant alkaloids that Western science has only recently rediscovered.

Albert Hofmann, writing in *The Road to Eleusis*, further suggested that the hierophants might have processed the *C. purpurea* ergot with a simple water extraction, dissolving off the water-soluble alkaloids containing ergonovine and methylergonovine, the principal hypothesised psychoactive compounds. Ergonovine, also known as ergometrine or ergobasine, is a psychoactive lysergic acid amide similar in structure to, but far less potent than lysergide, or LSD. The proposed water-extraction process would also supposedly have prevented the toxic ergopeptine alkaloids of *C. purpurea*, abortifacient and dangerously vasoconstrictive but not at all psychedelic, from entering the potion. Ergopeptine alkaloids such as ergotoxine and ergotamine were the agents responsible for the recurring plagues of ergotism known throughout European history, so it may safely be assumed that they were somehow excluded from the *kykeon*.

Hofmann also proposed an alternate hypothesis that the *kykeon* might have been prepared from another species of ergot (*Claviceps paspali*), growing not on barley (or only rarely) but on wild grasses of the region such as *Paspalum distichum*. The hypothesis appeared attractive because *C. paspali* produces a much more psychedelic blend of alkaloids than *C. purpurea*, similar to that contained in the redoubtable Western hemisphere psychedelic plant of the Aztecs, *ololiuhqui*. In addition, the toxic ergopeptine alkaloids are largely if not completely absent in this ergot species.

This paper examines these hypotheses in light of more recently published material, and introduces additional considerations in an attempt to take the Eleusis debate to a level from which further research might lead to a breakthrough. New hypotheses concerning the composition of the *kykeon* and the ways it might have been prepared are advanced. We will attempt to evaluate what is known and suspected about the possible composition of the *kykeon* employing several important clues gleaned from Greek literature and modern research. Such clues need to be kept in mind during the evaluation of *kykeon* hypotheses, for considered apart from these clues, even the proposal that an ergot was the psychoactive ingredient can be doubted, and the way left open for the suggestion of several other possible psychoactive plants as the key ingredient. Indeed, certain authors have done so, in a paper to be discussed below.

The Clues

The fact that the Rite was practised like clockwork for large numbers of communicants (a thousand or more, in later years), and for nearly two millennia must require that the psychedelic entity employed was of constant characteristics and dependability, that sufficient quantities could be easily obtained every year independent of varying conditions, and that the method of preparation was also little subject to the vagaries of error or changing conditions.

Other facts relevant to the *kykeon* and the Rite, and the two hierophant families which controlled and kept secret the recipe for the sacrament for nearly two millennia, are several. Of special importance is the fact that the recipe *was* successfully kept secret for this very long period, when documentation shows that many would probably have desired to discover its particulars. The *kykeon*, or perhaps the secret of its preparation, was apparently stolen on at least one occasion for use at Athens "cocktail parties," profaning the sacred rite and its potion. If the *kykeon* could have been simply duplicated, if it were obvious which ingredients were used and how they were prepared, it would presumably have not been necessary to steal it, and its profane use might well have become common. We must assume not only that the recipe *was* effectively kept secret, but more importantly that some critical feature of the recipe was *easy to keep secret*. Perhaps the true identity of the active ingredient, but more likely the way in which it was processed or prepared was the key secret. Such processes must of course have been simple and reproducible, in line with technical abilities of the time, yet not easily observed by spies nor intuited by outsiders.

Further clues can be gleaned from Greek literature, and pertaining to the characteristics of ergot and the way and frequency with which it infests its hosts, and similar botanical characteristics of other proposed active ingredients such as *Psilocybe* mushrooms. I shall introduce these further clues as necessary during the discussion to follow.

The Objections

Recently, objections have been raised concerning the ergot hypothesis, most notably in an article by Ivan Valencic in *Jahrbuch fur Ethomedizin und Bewusstseinsforschung*: "Has the Mystery of the Eleusinian Mysteries Been Solved?". The main complaints of the author are as follows, in the order in which they appear in the article:

> Objection 1. The proposed psychoactive ingredients of *C. purpurea*, ergonovine and methylergonovine, are not exceptionally psychedelic when ingested as synthesised compounds.
>
> Objection 2. Preparations of *C. purpurea* itself have not been made and pharmacologically tested which demonstrate it might have been sufficiently psychoactive to have provided the undoubted powerful psychedelic reaction to the *kykeon*.
>
> Objection 3. These same proposed active ingredients, at the doses necessary to produce the moderate psychoactive effects they are capable of producing, also produce significant discomfort, cramping, and lassitude. Presumably the effect of the *kykeon* was a quite enjoyable experience or it wouldn't have been sought after by rich Athenians to entertain guests, nor would the experience of the sacrament at Eleusis have been written about so glowingly by everyone who partook of the Rite and its potion.
>
> Objection 4. In addition, ergonovine at these dose levels is capable of producing spontaneous abortion, and since women were often initiates in the Rite and no such problems were ever described, we must doubt that the full story has been discovered in the *C. purpurea* hypothesis as advanced in *The Road to Eleusis*.
>
> Objection 5. Concerning the *C. paspali* variant of the hypothesis, it is objected that this fungus is known to produce tremors in cattle grazing on infected grass, and, similarly to *C. purpurea*, that no one has processed the fungus into a preparation shown to be psychedelic to a degree in agreement with the properties of the *kykeon*.

> Objection 6. The reference to the composition of the *kykeon* in the Homeric *Hymn to Demeter* is obviously incomplete, or even false, the recipe given there containing only water, barley, and a type of mint known to be at most only slightly psychoactive. It is thus proposed that this formula was merely a red herring, a way to deceive and disguise the true recipe. Barley may have had nothing to do with the true ingredients. Thus other psychedelic entities such as *Psilocybe* mushrooms or even opium must be considered as possibilities.

These would appear to be important reservations. And as the author points out, both the *C. purpurea* and *C. paspali* hypotheses are conspicuously testable, yet the only testing that has been accomplished has not produced very promising results. (An overview of several self-experiments with the proposed ergot alkaloids is given in Valencic's article, as well as in part 2 of this essay.) Let me work backwards through these objections, and bring to bear the clues I have mentioned.

Analysis

It is only possible to entertain objection 6 if we believe that the lack of positive results of testing the two ergot hypotheses precludes further experimental developments. Indeed, this appears to be Valencic's position as he concludes that the ergot hypotheses are "not very likely," and he "agree[s] with Robert Graves and Terence McKenna that there exists also reasonable possibility that psilocybian mushrooms might have helped to produce the astonishment and ecstasy in ancient initiates..." Given that the references to barley and mint in the *Hymn to Demeter* fit well in several respects with the *C. purpurea* hypothesis, and that further evidence from Greek literature as discussed by Carl Ruck in *The Road to Eleusis* also implicates barley and mint, more than mere "doubts" should be required before insinuating that the recipe of the *Hymn to Demeter* was mere fabrication. The best and most believable lies or deceptions are ones closest to the truth, and even better are deceptions which actually are the truth disguised by the way of telling, or by leaving out some critical detail. If the *Hymn to Demeter* specifies barley, it is very likely that the *kykeon* has *something to do* with barley.[2] *Psilocybe* mushrooms have no relationship with barley whatsoever. And the mint specified in the recipe also would support the ergot hypothesis, since mint is a known remedy for the slight nausea often encountered with various lysergic acid compounds including the psychedelic ones as well as ergotamine taken as a remedy for migraine. The preponderance of evidence indicates we must further explore the ergot hypothesis, rather than abandon it for other possible psychedelic plants.

The proposal that the barley-mint recipe was a total fabrication designed to conceal the true secret also begs the question of why barley and mint would have been chosen as the fictitious ingredients. Why not other herbs, or plants, or even rare substances that were generally unavailable? Why implicate a principal foodstuff if in reality there were not the least connection? The barley-mint recipe cannot be abandoned so easily. In addition, some facts relevant to *Psilocybe* mushrooms, discussed below, make this alternate hypothesis rather far-fetched.

Objection 5 has recently become a moot point, as it has been convincingly shown that *C. paspali* was almost certainly not present in ancient Greece, neither its host *paspalum* grass.[3] *C. paspali* might well have made a suitably psychoactive potion due to its alkaloidal content, very similar to the Aztec psychedelic, *ololiuqui*. Although several self-experiments with *ololiuqui* (seeds of two species of morning glory) or with its purified alkaloids ergine and isoergine have been inconclusive (see the mentioned examples in part II of this paper), I can personally assure readers that the alkaloids of *ololiuqui* are, when prepared correctly, quite capable of producing the entire range of powerful psychedelic effects. Ergine and its stereoisomer isoergine are the two principal psychoactive compounds of *ololiuqui*, and also the major alkaloids found in *C. paspali*, yet they are not found in *C. purpurea*. But the story of ergine and isoergine might be more important than has previously been suspected, as will be evident from what follows here.

Objections 1 through 4 all depend on the assumption that ergonovine and methylergonovine are the active principles resulting from the processing that was required to make the *kykeon* from *C. purpurea*. But self-experiments with these compounds, and the lack of other suitably psychoactive chemical candidates in *C. purpurea*, seem nearly to disqualify the ergot hypothesis from serious consideration. We seem to be at an impasse, with the best hypothesis marred by experimental weaknesses, and alternate hypotheses rapidly diverging from our most solid clues.

Although one might imagine that *C. purpurea* naturally parasitising barley in ancient Greece contained a more psychoactive blend of alkaloids than has been found in *C. purpurea* grown and tested in recent times, the fact that the psychedelic *kykeon* was so reliable for so long would indicate a corresponding long term reliability of content of the fungus which should thus have continued into the present, *i.e.*, today's *C. purpurea* is very probably quite similar in its alkaloidal spectrum to that of the same fungus parasitising barley in ancient Greece. Thus some suggestions that the known variability of ergot with varying hosts and growth conditions might resolve the question is unconvincing. Similarly unconvincing are proposals that the Eleusinian priests had discovered and cultivated some other species of ergot.

Further Considerations

Following are some further observations which should guide hypothesis formation: facts and probabilities drawn from what we know about ancient Greece, the Rite, the biology and chemistry of ergot and other proposed psychedelic plants, and other sources.

Relatively large amounts of the ingredient were needed,[4] at a certain time of year, on demand. This fact argues against wild mushrooms or wild ergots such as *C. paspali*, and in favour of the hypothesis that the priests harvested the item from a plentiful, known, reliable, naturally-occurring and nearby supply. It is possible, however, that they had discovered how to augment supplies by simple procedures.[5] Even with modern agricultural techniques, *C. purpurea* remains a common infestation of cereal grains, thus we may assume that this ergot was also common in the barley of the Rarian harvest, no doubt a large one. Thus even with a mild ergot infestation, sufficient quantities should have been obtainable. The grain harvest, and consequently the possibility to select out the ergot therein, occurs in late spring or summer, just in time for the September Eleusis celebration. The separation of ergot from the grain might also have been easy for the priests to do without undue observation, or without raising suspicions of what it was to be used for. A "purification" of the harvest in which "malformed grains" (see again footnote 1) as well as other contaminating material were removed might have been a cover-story.

However, as discussed above, *C. purpurea*, in its natural state, contains an alkaloidal content that is at best only moderately psychoactive, and with unfavourable toxic side-effects. *C. paspali* would have been a far more likely candidate on the basis of its alkaloid content, but is now ruled out. In fact, we might have ruled out naturally-occurring *C. paspali* on the basis of availability: Growing wild, it probably wouldn't have been reliable or copious enough to produce the quantities necessary, and collecting large amounts would have entailed scouting the countryside at great length, an activity easily observed by spies, and thus the recipe become easily known. Similarly, if *C. purpurea* were the active ingredient, and easy to process with a simple water extraction as suggested by Hofmann, could the secret so easily have been kept for so long?

Psilocybe mushrooms are ruled out, however. Several aspects of the Rite and what we know about wild mushrooms make the *Psilocybe* hypothesis unlikely. The rite was held every year and at a precisely defined time in the month of September. Thousands of specimens of even the strongest *Psilocybe* mushrooms would have been needed, at a time of year when the climate of Greece was just barely subsiding from the summer heat and dryness. Although cooler mountainous areas of 1000 meters in altitude are within ten or twenty kilometres of Eleusis, it is very unlikely that such vast quantities of an uncommon wild mushroom could have been located so early in the year, like clockwork and in advance of the autumn rains, or that the hierophants could have collected such quantities every year and transported them back to Eleusis without the secret of their activity escaping. And as anyone who has collected wild mushrooms knows, they seldom appear on-schedule, in such dependable quantities, even when an area known to produce a certain variety has been identified.

If it is proposed that a *Psilocybe species* growing on the dung of domesticated herbivores might have been the *kykeon*'s secret, again we run into trouble. In the typical summer climate of Greece, herbivores' excretions would have dried so quickly in the heat that the hierophants would have had to irrigate them to even hope that mushrooms would appear, and they would have been lucky to produce even a handful under those conditions. And once again, it would have been a difficult operation to keep secret. After autumn rains, in November and December, animal dungs might well have produced their fungal consequences, too late for the rite unless we hypothesise that December's *Psilocybe* was stored for the following year: Again, a highly unlikely hypothesis for reasons too obvious to mention. But this observation does indicate another argument for ergot: the easily-dried sclerotia of ergot *are* quite capable of being stored, retaining their alkaloids for considerable periods, and certainly *could* have been stored for at least a year without preservatives, in containers of minimal size easily secreted in the confines of the temple. Thus stored ergot might have augmented supplies in lean years.

And of course the idea that the hierophants had perfected the cultivation of *Psilocybe* mushrooms is even more fantastic. I doubt that such a hypothesis even needs to be criticised. But one final argument might indicate that there weren't even any *Psilocybe* of note growing in Greece at the time. As noted in *The Road to Eleusis*, (p. 42) the Greeks were well acquainted with a wide range of inebriants and herbs, and how to prepare "wines" suitable for many purposes. If *Psilocybe* mushrooms had been common enough to use for the *kykeon*, they would no doubt have long been known and written about, and their secret impossible to keep. Neither the *Psilocybe* hypothesis, nor the hypotheses of naturally-occurring alkaloids of *Claviceps purpurea*, nor naturally-occurring *Claviceps paspali*, nor of course any of the other hypotheses that the *kykeon* was some kind of alcoholic beer made from barley, or that it was merely symbolic, etc. etc., will suffice.

We seem to have shown that *C. purpurea* is the most likely *kykeon* candidate while simultaneously proving its insufficiency to deliver a safe dose of alkaloids powerful enough to produce the full range of psychedelic effects. What is amiss? The most straightforward hypothesis is that the Greek priests had discovered some way to *transform* naturally-occurring supplies of *C. purpurea*: they must have found a technologically-simple process to alter the alkaloidal spectrum of ergot. At first this surely sounds like an impossible idea, yet some ergot alkaloid research of the 1930s, recently confirmed and until now overlooked by the various participants in the Eleusis debate, provides the key.

Ergine and Isoergine

Years ago, with the threat of my impending draft into the U.S. Army for an extended tour of Southeast Asia, I decided instead to "go on the lam," and departed for Mexico with the intention of researching the distribution and chemistry of some of the famous Central American psychoactive plants such as *ololiuqui*. It was during the course of these investigations that I prepared astonishingly powerful extracts of *ololiuqui*, alluded to above. I had also been interested in the possibility of hydrolysing the alkaloids of *ololiuqui* in an attempt to prepare pure lysergic acid. This is a simple process, requiring only that the extracted ergine / isoergine content of the seeds be boiled for some time with a strong base such as potassium hydroxide. Although my researches were ended prematurely by unfortunate events, an important result for the present question was that I became well-acquainted with the chemical literature concerning lysergic acid, its production via hydrolysis, and the various conversions possible when treating ergot alkaloids in differing conditions.

I learned from the early chemical literature that the base-catalysed hydrolysis of ergopeptine alkaloids typical of *C. purpurea* apparently proceeded via a two-step process, the first and most rapid step resulting in ergine[6] which was then more slowly hydrolysed to lysergic acid. The discovery of ergine was in fact accomplished in such a manner: Early work in the 1930s had found that treating ergotoxine (a mixture of three ergot alkaloids from *C. purpurea* extracts) with a base such as potassium hydroxide, yielded both lysergic acid and ergine.[7] The details of the various experiments indicated that longer reaction times and higher temperatures favoured the complete transformation to lysergic acid, while short reaction times and lower temperatures resulted in significant amounts of ergine. Subsequent unpublished work by myself indicated the strong dependence of the hydrolysis on temperature, but weak dependence on base concentration.

Over the years I gradually forgot about these results until recently, musing over the objections to the theory of *The Road to Eleusis*, the "Ergine Hypothesis" suddenly appeared to me as a possible key to countering the objections. The hierophantic priests might well have discovered how to achieve a partial hydrolysis of the mostly toxic alkaloids of *C. purpurea*, resulting in an extract of ergot containing a blend of psychedelic compounds closely similar to the Aztec's *ololiuqui*. The partial hydrolysis might thus also eliminate the toxic ergopeptine alkaloids, converting them to psychoactive ergine and isoergine.

But how were the hierophants to accomplish this feat, seemingly not duplicated until the 20th Century? It must have been a technologically simple procedure, and employed common ingredients, yet been easy to keep secret. Although potassium hydroxide was surely not available to the Greeks, the ashes of wood fires certainly were, and in fact a mixture of wood ash in water results in a solution of potassium of reasonably strong basicity. Is it possible that merely digesting powdered ergot with wood ash and water (and possibly wine containing 10% or so of ethanol to improve the solubility of the alkaloids), heating the mixture for a short period and then filtering off the liquid might have been the method of mixing the *kykeon*? I decided to ask the opinion of a colleague, an associate professor of chemistry at Loyola College in Maryland, and author of *The Chemistry of Mind-Altering Drugs*.

2. It should be remembered that the appearance of ergot on its host has all through history led to the conclusion that ergot was merely malformed or sun-burned or "rusted" grains of the cereal host in question. It wasn't until the 20th Century that ergot was generally recognised as another species altogether, a fungal parasite of the grain on which it appeared. Thus the Greeks very probably also made this error.
3. See Francesco Festi & Giorgio Samorini, "*Claviceps paspali* and the Eleusinian Kykeon: A Correction." *The Entheogen Review*, Volume VIII, Number 3, Autumn 1999.
4. A quick calculation of quantities necessary: Total alkaloid yield of *C. purpurea* may be about 1%, most of it ergopeptines with only a few percent ergonovine. The dose of ergine / isoergine (the active ingredients according to the arguments to follow concerning the method of preparation) should be between 1 and 5 mg as it has been recorded that its potency is about 1/10 that of LSD. Thus, per 1000 Eleusis participants we require up to 5 gm total alkaloids, corresponding to 0.5 kg of ergot. Modern yields of ergot from cultivation on rye can yield hundreds of kilograms per hectare. Thus it seems reasonable that the Greek priests could easily have harvested enough ergot from the nearby barley fields. Ripe ergots can easily be collected from the grain in the field, as they fall off the grain head even with strong wind. By contrast, the ergonovine hypothesis of *The Road to Eleusis* would require far greater quantities of *C. purpurea* since ergonovine only represents a small fraction of the alkaloid content of the fungus.
5. A likely possibility is that the priests had discovered how to spread an ergot infection using a water solution of the *honeydew* produced. Early in the growth of ergot on grain, the fungus causes the production of droplets of a sticky syrup on the grain heads, and insects attracted to this exudation transmit the ergot mycelium therein to other developing heads of grain. A solution of a few drops of honeydew in a litre of water produces a mixture that when shaken or sprayed onto other developing grain heads readily spreads the infection.
6. The process also produces isoergine, for in basic solution all such amides of lysergic acid rapidly approach an equilibrium mixture of the two associated stereoisomers.

Entheo-pharmacological Considerations

In agreement with what Peter Webster has discussed in the preceding portion of this article, it seems to me that it is quite possible that a "potion" containing as its main active ingredient lysergamide (ergine, the active entheogen in *ololiuqui*) and free from any more toxic alkaloids, could be reliably produced from ergot harvested from *Claviceps purpurea* infected barley using materials and processes available to the ancient Greeks. That is, such a procedure seems chemically possible for reasons which will shortly be presented in detail - although, of course, this possibility cannot be truly proved without actually carrying out a series of experiments in which ergot would be processed as hypothesized. Chemical possibility is, of course, not historical fact or even historical plausibility, but it can at least establish historical possibility.

A first objection to the suggestion that the Eleusinian mysteries owed some of their powerful effects and passionate loyalty to the entheogenic action of lysergamide in the *kykeon* is that lysergamide is not really a very good entheogen, certainly not when compared to the psilocybin in *nanacatl* or the mescaline in peyote. Indeed, the few documented descriptions of *ololiuqui* intoxication are far less dramatic than those employing LSD, mescaline, or psilocybin. Here is the full record, as far as I have been able to ascertain:

1. In 1955, Humphrey Osmond[1] took 60 to 100 seeds and experienced, according to Schultes and Hofmann, "a state of apathy and listlessness, accompanied by increased visual sensitivity. After about four hours, there followed a period in which he had a relaxed feeling of well-being that lasted for a longer time."[2]
2. Hofmann compares the effects of *ololiuqui* rather unfavorably with those of LSD in his book, *LSD: My Problem Child*[3] His description is as follows: "After the discovery of the psychic effects of LSD, I had also tested lysergic acid amide [lysergamide] in a self-experiment and established that it likewise evoked a dreamlike condition, but only with about a tenfold to twentyfold greater dose than LSD. This effect was characterized by a sensation of mental emptiness and the unreality and meaninglessness of the outer world, by enhanced sensitivity of hearing, and by a not unpleasant physical lassitude, which ultimately led to sleep." As for the effects of the Mexican morning-glory seeds, he continues: "The psychic effects of *ololiuqui*, in fact, differ from those of LSD in that the euphoric and the hallucinogenic components are less pronounced, while a sensation of mental emptiness, often anxiety and depression, predominates. [Such]...weariness and lassitude are hardly desirable effects...in an inebriant."
3. Solms, in a systematic comparative study of the psychopharmacology of lysergamide, confirmed Hofmann's impressions, concluding that it "induces indifference, a decrease in psychomotor activity, the feeling of sinking into nothingness and a desire to sleep... until finally an increased clouding of consciousness does produce sleep."[4]
4. Hofmann also tested the effects of isoergine (which is formed in much smaller amounts with ergine in the basic hydrolysis of ergot shortly to be described) and found that 2.0 mg orally produced a syndrome not very different from ergine, characterized by sensations of "tiredness, apathy, a feeling of mental emptiness and the unreality and complete meaninglessness of the outside world."[5]

These seem to be the effects of ergine and/or isoergine when taken in the context of a scientific, clinical effort to disclose their psychopharmacology; and we can therefore presume that these would also be the effects of our hypothesized κυκεών under the same conditions. For the process we will describe would transform all the ergot alkaloids into ergine or isoergine. Even ergobasine (lysergic acid hydroxyethylamide, found in small amounts in *ololiuqui* and in some samples of ergot from Central Europe) would be converted to ergine. The only other likely psychoactive ingredient in the κυκεών would be wine.[6]

But these rather humdrum effects of ergine taken in the context of a dispassionate clinical experiment by volunteers already well-acquainted with the overwhelming visual and psychological effects of LSD and psilocybin by no means preclude the possibility, even the likelihood, that a potion containing ergine could powerfully catalyze and amplify the religious experience of the Eleusinian communicants of ancient Greece. Among the most important reasons for affirming this are the following:

Clinical versus Ritual Setting

There is no doubt that *ololiuqui* has been valued for centuries as a sacred entheogen in Oaxaca by *curanderos* of the Zapotec, Chinantec, Mazatec, and Mixtec tribes. And the principle psychoactive agent in *ololiuqui* (*Rivea corymbosa*, *Ipomoea violacea*) is just what we propose to have been the active agent in the *kykeon*: ergine (with smaller amounts of isoergine).[7] If, to the vague and directionless alteration of mental state provided by ergine in the jejune setting of the research clinic, there is added the governing mind-set of religious belief coupled to the external setting of a centuries-old ritual, participants can and do experience a many-fold entheogenic intensification of the awe and dread felt before an ecstatic theophany of the *mysterium tremendum et fascinans*.

Indeed, other *pharmaka* with far less likely *a priori* plausibility if judged solely by their clinical psychopharmacology have been exploited for millennia in various cultures for their entheogenic effects: I am thinking particularly of *Amanita muscaria* (which despite its likely identity with the archetypical Vedic entheogen, *soma*, produces in secular settings only a bizarre state of incoherent delirium) and the presently much-despised *Nicotiana*, which "is not generally considered to be a hallucinogen. Yet, like the sacred mushrooms, peyote, morning-glories, *Datura*, ayahuasca, the psychotomimetic snuffs, ... tobacco has long been known to play a central role in North and South American shamanism, both in the achievement of shamanistic trance states and in purification and supernatural curing. Even if it is not one of the "true" hallucinogens ... tobacco is often conceptually and functionally indistinguishable from them. We know that Indians from Canada to Patagonia esteemed tobacco as one of their most important medicinal and magical plants and that some employed it as a vehicle of ecstasy."[8] Of course, many of these groups used tobacco or tobacco extracts in massive dosages in order to deliberately provoke a near-death experience. Yet, even in moderate amounts, and despite endless condemnation from Christian missionaries and Surgeons General, tobacco continues to be revered to this day as an integral part of the peyote ceremony by many adherents of the Native American Church.

Fasting

The *kykeon* was drunk *after a nine-day fast*. It was perhaps the sole beverage/food which broke that nine-day fast, and the drinking of the *kykeon* took place at the peak of a most solemn religious ritual.[9] Probably few or none of the readers of this article have carried out a strict fast for nine days in the integral context of a life-transforming religious observation, and still less likely have any of them followed this by consuming, at the approach to the Holy of Holies, a dreaded sacrament with potent mind-altering effects. Peter Webster has given testimony to being himself deeply affected by *ololiuqui*. Let me add my own testimony to the effects of set, setting, and fasting:

About a quarter of a century ago, in the company of a dozen or so other recently-ordained Jesuits my age, I entered upon the consummatory event of the Jesuit spiritual training, the second and final 30-day Ignatian retreat. During the first part of Ignatius's *Spiritual Exercises*, which are the guide for this retreat, the "exercitant" is expected to unceasingly consider his utter unworthiness before God of aught but damnation, all the while living in total silence and solitude except for attendance at Mass and brief colloquies with one's director. Following these directives to excess, I soon fell prey to the Moloch of Christianity's most negative doctrines. By the third day, I had ceased eating, attending services, or talking with my director, walking alone instead for miles each day lashing myself with doubts and despair. After more than three days of eating nothing, I reached a rather grim metastable state at the nadir of resigned desperation: if I could never attain the love of/for God, I would simply go through the dead motions of devotion during the rest of the retreat. It was dawn. For the first time in four days, I ate, with total absence of any appetite: one slice of toast and a cup of sugarless black coffee. As I stared then blankly at the blank pages of my retreat journal, I was suddenly and overwhelmingly "transported." In some indescribable way and for what seemed like only a few seconds, I was suspended from the world of space and time and experienced myself in the immediate presence of "God." I say "God" because It was nothing at all like anything my imagination had ever before constructed. But it was *true* with an ineluctable certitude I have never been able to doubt. And it was probably the most pivotal moment of my life: whatever I have done since (including leaving the priesthood many years later) can be traced in some sense back to this experience; everything I have thought since of myself or "God" has been radically different. Was it the set and setting? Of course. Was it the fasting? I doubt that it would have occurred had I not fasted those four days - but then, I would never have fasted those four days (it was a completely spontaneous lack of interest in eating, not a planned exercise) had I not been gripped by an overpowering mind set which was completely reinforced by the setting.

Perhaps the experience was even to some extent the "entheogenic" effects of black coffee and toast. In the early part of the last century, week-long fevers could leave a sick person delirious and emaciated, and Thomas De Quincey writes in 1822, by way of comment on his own opium habit, that "Some people have maintained, in my hearing, that they had been drunk upon green tea; and a medical student in London, for whose knowledge in his profession I have reason to feel great respect, assured me, the other day, that a patient, in recovering from an illness, had got drunk on a beef-steak."[10] I purchased a few seconds of Eternity with four days of fasting and a cup of black coffee; had I paid with nine days, ergine, and Pramnian wine, might I not have bought an hour?

I am certain that the duration and perhaps even the depth of this experience (although the second aspect seems much less quantifiable than the first) would have been greatly intensified if, say, I had drunk a cup of peyote tea instead of black coffee. Indeed, when I try to imagine what would have been the likely outcome of such a switch in beverages I am terrified and find myself quite grateful that only coffee was available. As Huston Smith says, "awe is not fun,"[11] and the experience was sufficiently awesome as it was.

Two reasons convince me that an entheogen would have powerfully intensified the duration and particularly the likelihood of such an experience (for in-depth experiences of this sort are not that common, even among the many earnest Jesuits who have made this final retreat - at least not among the Jesuits I knew and know from my generation). The first is that I am now able to extrapolate backwards in time from a number of quite beautiful, awesome - even occasionally terrifying - religious theophanies which I experienced years later under the influence of entheogens.[12] The psychological and spiritual set and setting of these later experiences could not approach the once-in-a-lifetime situation of the retreat experience described above (although it was intentionally and earnestly religious), and so I was all the more impressed that the simple ingestion of a plant or chemical could invoke in such ordinary circumstances so profound an emotional and religious response.

The second reason is of course the famous "Good Friday Experiment" of Walter Pahnke, the "Miracle at Marsh Chapel," where a group of seminary professors and students, under double-blind conditions, were given either psilocybin or an active placebo[13] immediately before a three-hour Good Friday service. Those receiving the true entheogen experienced an intensity of religious emotion and exaltation greatly exceeding in statistical significance the experience of the controls, and they evaluated their experience just as highly when they were interviewed in a long-term follow up by Rick Doblin some 25 years later.[14] This is as close to a scientific demonstration of the efficacy of entheogens in intensifying and facilitating religious experience as has yet been conducted. And yet, one can only guess how much even this profound entheogenic catalysis of a religious setting might have been still more amplified had it been experienced following a multi-day fast!

Sacred versus Profane Setting

No one disputes that ergine unmistakably and profoundly alters everyday consciousness - the only dispute concerns whether this alteration has, considered in isolation, properly "entheogenic" qualities. But as a matter of fact, even those psychoactive agents which by general consensus produce an alteration of consciousness most closely resembling and most likely productive of religious ecstasy (mescaline, psilocybin, LSD) *fail*, in the vast majority of cases, to produce anything like a religious experience when taken in a totally profane context. I am thinking of the hundreds of first-hand written accounts the college students I teach have given me over the years describing their use of psilocybe mushrooms or LSD. I would characterize fewer than 20% as empathogenic, and fewer than 10% as entheogenic. Doubtless the common use of large amounts of alcohol at the same time has much to do with this, but I suspect the usually banal intra- and interpersonal context, a context augmented by a nearly total absence of prior religious experience in any depth, is what succeeds in quenching so utterly the sacred flame. All of which is to say that entheogens, even the best of them, cannot create the "divine within" in and of themselves (to this extent, "entheogen" is a misnomer or an overstatement) absent anything at all numinous in set or setting. *Odi profanum vulgus, et arceo* admonishes Horace.

Synergine

It may seem to the reader that the arguments I have been making here could be turned on their head: if set and setting are so important to religious experience, why is there any need to hypothesize the presence of an entheogenic drug in the *kykeon* at all? Why? Because herbs, drugs, and potions *were* widely investigated in the ancient Greco-Roman world; because the *kykeon was* regarded with awe and dread as having an intrinsic psycho-spiritual potency (in a culture in which the distinction between divine or demonic possession and psychopharmacological alterations of consciousness barely existed: for most people, there was only the former, even with regard to Dionysian alcohol); and, consequently, because in such a cultural context the hierophants of a so deeply a revered and successful initiatory rite as that of Eleusis *must* have devoted their best efforts over the millennia of its existence to endow the *kykeon* with the most powerful and appropriate *pharmaka* they could find. Reflecting again on the results of Walter Pahnke's study, it is clear that when an appropriately intense set and setting are present, nearly every participant who receives an entheogen experiences an unforgettably transformative theophany. On the other hand, those who experience only set and setting have such intense experiences relatively rarely. The stories and testimony from the Eleusinian participants, filtered through the darkening lens of history, seem to suggest that mystical and near-mystical experiences were so usual that we must postulate the synergetic and catalytic effects of an entheogen.

For all the numerous descriptions of entheogenically catalyzed religious experience suggest that the triad of *set, setting*, and *drug* (which last of course becomes an "entheogen" only in virtue of a particular context of set and setting) operate as independent variables, since each is indispensable. Yet despite this independence, they act in consort to *a*ffect and *e*ffect the final outcome not merely as their arithmetic sum but (particularly in the case of entheogenic drugs) in a deeply interpenetrating *synergisis*. Participants at Eleusis came away convinced that they had seen and *experienced* ("hierophant" means one who makes the Holy itself *manifest, to be seen*),[15] in a numinous revelation, that they were individually destined for happiness after death. This is extraordinary in Greco-Roman religiosity, otherwise striking for its near hopelessness regarding the fate of the individual after death: *Immortalia ne speres*, admonishes Horace again; and yet "the Mysteries of Eleusis, ... both to the community and to the individual, ... supplied confidence in the face of all-devouring death."[16] And the experience commanded immense loyalty: quite astonishingly, the secrets of the Eleusinian mysteries were never divulged. It seems to me that Something, something well beyond the sacrifice of a few animals and the attendance at a solemn ritual, must be invoked to account for this: what better Something than that central feature of so many primordial religions throughout the world - an entheogenic sacrament? And hence, abandoning all semblance of etymological propriety, and employing the argot of the pharmaceutical corporations, we might christen the generic drug ergine, when employed exclusively as an entheogen, as *Synergine*.

Chemistry

Due credit should be given to Peter Webster for his laudably tenacious and accurate memory. When he first suggested to me that ergine could be isolated by alkaline hydrolysis of ergot alkaloidal material, I was somewhat skeptical - why, if the other peptide bonds of ergot had been hydrolyzed, would not the amide linkage of ergine itself be hydrolyzed and the product be lysergic acid itself? Other organic chemists I proposed this to felt likewise. But Peter was right: ergine, not lysergic acid, was in fact the first characteristic ergot compound to be isolated in pure form. In 1932, Sidney Smith and Geoffrey Willward Timmis of the Wellcome Chemical Works in Dartford, UK, were the first workers to report a non-trivial product from the degradation of ergot alkaloids.[17] The crystalline compound resembled the ergotinine or ergotoxine from which it was isolated in that it was an alkaloid which displayed all the characteristic color tests for the presence of an indole ring system. However, when its effect on rabbit uterine contractions were tested it was disappointingly found to be over 400 times less potent than ergotoxine. They named the compound *ergine*; later, it would be shown to be the simple amide of lysergic acid.

Two years later, Jacobs and Craig at the Rockefeller Institute in New York confirmed the results of Smith and

Timmis and found that by using aqueous instead of methanolic alkali they could get a better yield of a new substance, lysergic acid.[18] Later communications between these groups in England and the U.S. allowed a determination that ergine was indeed the simple amide of lysergic acid.[19] Since the yield was greater and since lysergic acid proved to be a far more useful starting-point for further studies either of ergot itself or of any new derivatives with its properties, little further attention was given to the procedure of Smith and Timmis; instead, all efforts were directed to improved methods of isolating the commercially important lysergic acid. (Indeed, these efforts continue to this day, and in the course of writing this article, Peter Webster put me in touch with Vladimír Kren, a highly regarded ergot researcher from the Czech Institute of Microbiology, who sent us a preprint of an article disclosing a procedure for maximizing the yield of lysergic acid from ergot.[20]) It appears that preoccupation with the production of lysergic acid has led to some chemists to forget that simpler and milder versions of these same procedures will result in the production of ergine - *and it is precisely these simpler and milder conditions which would be accessible to the hierophants of Eleusis*.

How did the experimental conditions of Smith and Timmis (ST), in which ergine was produced from ergotinine, differ from those of Jacobs and Craig (JC), in which lysergic acid was produced from ergotinine? Fundamentally, the difference was a matter of concentration and temperature. ST refluxed ergotinine for one hour in a 1.0 *M* solution of potassium hydroxide (KOH) in methanol, which boils at 65°C, while JC refluxed ergotinine for an hour in a 1.4 *M* solution of KOH in water, which of course boils at 100°C. The reason that ST used methanol is that pure crystalline ergotinine[21] is insoluble in water and unreactive even in boiling aqueous KOH. JC found that the resinous material remaining after ergotinine was rapidly dissolved in methanolic KOH and then evaporated would slowly dissolve with liberation of ammonia in boiling aqueous 1.4 *M* KOH. Martínková, Kren, *et al*. have been able to maximize the production of ergine/isoergine from ergotamine by using a less concentrated solution of KOH. They produce a mixture consisting principally of ergine and isoergine (total: 10.3 g) with relatively small amounts of lysergic acid/isolysergic acids (total: 1.65 g) from 30 g of ergotamine by refluxing for two hours in a 0.60 *M* solution of KOH, the solvent being a 1:3 mixture of water:ethyl alcohol.[22] These results can be compared to a standard procedure for producing lysergic acid from ergotamine as given in Shulgin's TIHKAL, where 3.5 g lysergic acid is obtained by stirring 10 g ergotamine in a 1.2 *M* aqueous KOH at 70°C for 3 hours.[23]

We suggest that conditions of solubility, pH, and temperature which would be equivalent in effect to ST's process, and result in the conversion of ergot to ergine, could be readily obtained by boiling crude ergot for several hours in water to which the ashes of wood or other plant material, perhaps barley, had been added. These are, of course, conditions easily achieved by the hierophants of Eleusis. Why would these conditions produce ergine? Wood ash contains potassium carbonate (pearlash), a strong base which for millennia was the usual material used to produce soap from animal or vegetable fats - an hydrolysis process (saponification) almost identical to the hydrolysis of the amide bonds of ergot. Wood ash has a pH of about 12, while the 0.60 *M* KOH used by MK has a pH of almost 14. But the Greek priests would have employed water as a solvent, since distilled methanol or ethanol was then unknown, and the resulting higher temperatures (and quite likely longer cooking times, which would tend to concentrate both product and alkali reagent) would compensate for the less concentrated base. As for the solubility problem encountered by ST and JC, we suggest that it would not obtain when crude ergot was used instead of crystalline ergotinine. This is because crude ergot contains from 30-35% fatty acids[24] which would both solubilize the ergot alkaloids of their own accord and even more so by virtue of the micelles formed when these fats were saponified by the hot pearlash.[25]

Why would the hierophants consider ashes as a suitable ingredient in a sacred potion? We suggest the possibility that some sort of symbolism involving the resurgence of life from inanimate ashes may be involved. Kerényi points to a symbolic cluster of images surrounding birth in death, birth in fire, the ashes of the cremated votaries - all linked to the hope of life after death.[26] Persephone herself was looked upon as the goddess of fire, for "through her power the evil element was transformed into a kindly one."[27] Perhaps also the ashes symbolized the immortality which Demeter wished to bestow on the little prince Demophoön, who was able to thrive and grow without food as long as she secretly placed him each night in the fire like a log. When Demophoön's mother, Metaneira, observes Demeter's strange action and protests it, Demeter takes the boy from the fire - but now he is doomed with the rest of mankind to death. "Unknowing are ye mortals and thoughtless: ye know not whether good or evil approaches."[28] An augmenting motive to any of the preceding is simply the reverence naturally felt towards the ashes remaining after a whole-burnt offering to the gods on a sacred altar. These are not ashes to be simply disposed of as one would ordinary hearth ashes; they partake of the sacral nature of the offering, and it is natural to attempt to incorporate them in some further sacral function. The same instinct can be seen at work in the custom, observed to this day in the Roman Catholic tradition, of reserving the ashes of the palms blessed on Palm Sunday to be used on Ash Wednesday of the following liturgical season.

Would a potion containing enough ashes to hydrolyze ergot alkaloids be too basic and caustic to drink? We suggest several possibilities: most simply, a solution of potassium carbonate, if allowed to stand exposed to the air for a few days, would absorb enough carbon dioxide from the air to be turned into the relatively harmless potassium bicarbonate. Alternatively, as we have suggested earlier, a final addition of wine to the *kykeon* would neutralize the ashes, and this seems reasonable since in Homer the *kykeon* always contains wine. But in the Eleusinian myth, Demeter pointedly refuses to accept any wine to assuage her grief, since it would be "contrary to *themis*," against nature. This is thought to be more than just an expression of her unwillingness to drink a beverage of joy while still in grief for her daughter; rather, she declines because wine comes from Dionysus, and the rape of Demeter's daughter occurred on the Nysan Plain, where the Dionysian ground opened.29 Indeed, the *kykeon* is possibly the Eleusinian drink in part because it stood as an alternative in opposition to Dionysian wine. A third possibility, then, is that the final mixture was neutralized (more effectively in any case since it is more acidic) by the addition of vinegar, which as spoiled wine, might not offend Demeter and/or might even be symbolic of participation in her grief.

We finally come to the most technical part of this discussion, which is a mechanism justifying the chemical transformation of ergot peptide alkaloids into ergine/isoergine and non-toxic secondary products. For this I owe much to discussions with Professor David Nichols of Purdue University, whose numerous discoveries and internationally acknowledged expertise in the realm of psychedelic chemistry, and whose much greater familiarity with the chemistry of lysergic acid, make him far more qualified to address this issue than I.

We feel that the mechanism shown in **Scheme 1** accounts adequately for the known experimental facts. We show ergotamine with a hydrogen bond forming an eight-membered ring from the carbonyl at C-18 to the hydroxyl group at C-12' since Ott, Hofmann, and Frey have given persuasive evidence that this corresponds to the internal structure of the natural alkaloids.[30] There are three mechanisms which could be invoked to account for the partial hydrolysis of ergotamine to ergine. The first and simplest would be an attack by hydroxide at the amide N of lysergic acid (the N bonded to C-18), which would cleave off ergine in one step. However, as Dr. Nichols points out, this would involve an S_N2 attack at a quite hindered center. A more accessible point of attack would be the removal by base of the proton of the C-12' hydroxyl, which would induce a cascade effect essentially similar to what we have pictured in **Scheme 1**. However, part of the data provided by Ott *et al*. supporting the existence of an intramolecular hydrogen bonding at this center is the reduced acidity of this hydroxyl group at C-12' relative to the unnatural *aci* isomers, where epimerization at the C-2' center excludes the possibility of hydrogen bonding to the lysergic acid carbonyl for steric reasons. (Nonetheless, the OH in question is still considerably more acidic than an ordinary alcohol due to the cumulative electron withdrawal of a nitrogen and an oxygen on C-12'.) In any case, a third point of attack is possible that obviates both of these difficulties, and that is what we have drawn in **Scheme 1**, where solvent hydroxide removes a proton from the methyl group attached to C-2', thereby initiating a cascade of reactions (probably more or less simultaneous) involving the intramolecular hydrogen bond and leading to the enol tautomer of ergine, **1**, which rapidly rearranges to **ergine**. The other product of this cleavage is **2**, which should rapidly form **3** by extracting a proton from the solvent to regenerate hydroxide ion. **3** should itself be quite easily hydrolyzed in mild base to pyruvic acid and L-phenylalanyl-Lproline lactam, a harmless dipeptide formed from two essential amino acids. Under the mild conditions we envisage it is unlikely that any significant quantities of lysergic acid itself would be formed, since the amide bond of ergine would be hydrolyzed only very slowly by potassium carbonate. In any case, lysergic acid itself has almost no psychotropic effects.

Later, Odysseus is able to rescue them by first taking the antidote "moly" provided him by Hermes (*Odyssey*, x. 290, 316-320). Interestingly, the unusual word "moly" (μώλυ) is probably related to the Sanskrit *mulam*, a root, with the compound *mula-karma*, meaning the "magical use of roots." As well as making likely the presence of wine (or vinegar) in the Eleusinian sacrament, these citations show that an interest in drugs and potions added to a κυκεών is as old as the earliest Greek literature.

But unfortunately, the present legal and emotional climate is not as open-minded as it was in his day. And so I feel compelled to add by way of legal exculpation, and while emphasizing that the United States Constitution still grants the presumption of innocence, that entheogenic experiences do not necessarily involve the violation of any law, even laws which are arguably adjudged as excessive and immoral. (Cf. Husak, D., *Drugs and Rights*, [Cambridge Studies in Philosophy and Public Policy, D. MacLean, Ed.], New York: Cambridge University Press, 1992.) This is because 1) in some countries some entheogens are legal which are illegal in the United States; 2) some entheogens which are generally illegal in the United States are not necessarily illegal in all circumstances; and that 3) a number of quite effective entheogenic chemicals have never been declared illegal in any country - some of these are easily synthesized and others can be ordered from most of the major chemical supply houses.

The "active placebo" was nicotinic acid, which provokes a harmless flushing of the skin, tachycardia, and a rush of pounding blood to the head - symptoms which, although not very different from those caused by a cup of black coffee on an empty stomach - might suggest to the suggestible that they had taken a psychoactive drug. Using an active placebo was Pahnke's supererogatory effort to completely level the playing field between placebo and psychedelic. (Such probative integrity is rarely employed today: when, for example, a new drug with purported antidepressant effects is first tested on depressed subjects it is thrown into competition against a look-alike sugar pill which can have no psychic effect except through the subject's imagination. Nonetheless, those given placebo always show significant improvement over baseline, though not as much improvement as those given the genuine antidepressant. Such is the power of that most addictive of placebos, Hope.) However, in Pahnke's experiment, so intense and unique were the effects of high-dose (30 mg) psilocybin that within an hour it became apparent who had received the entheogen to both the controls and to the recipients of the active drug. 25. In modern times soap is made by treating fats with sodium hydroxide, NaOH, a base essentially as strong as KOH. But this process was developed by Leblanc and Chevreul only around 1790. Soap has been known since at least 300 BC, but had always been made by the much slower process of employing the potassium carbonate in wood ash, commonly called *pearlash*. After the Leblanc's work it became evident that soap could also be made from "lixivated pearlash" or *potash*, which was made by adding calcined limestone (lime, calcium hydroxide, CaOH) to the pearlash and precipitating out calcium carbonate. Lime was well-known to the Romans, who used it extensively in mortar for construction purposes, and oddly enough, the process of lixiviation was also known - it is mentioned by Pliny, who also discusses soap. But lixiviated pearlash appears not to have been applied to the production of soap until modern times. Indeed, the ancients did not use soap for cleansing; the usual process was to rub olive oil onto the skin after a bath, and then to scrape off the excess oil and dirt. Soap was used to some extent medicinally as a laxative, but primarily as an ointment for giving a bright hue to the hair - "rutilandis capillis." Pliny, *Historia naturalis*, xxviii. 51. There are numerous studies which have confirmed that micelles can greatly augment the rate of chemical reactions, particularly those which involve two phases as would be the case with our relatively insoluble material.

Barley-groats, water, and fresh mint. *Alphi* (or more fully, *alphiton*), *hydor*, and *glechon* (also called *blechon*). These are the known ingredients for the Eleusinian potion, the mixed drink or *kykeon*; these were the elements publicly announced and not part of the secret. Symbolically, the two plants represent various dichotomous antitheses that the aqueous *kykeon* mediates. First, the botanical, with the cultivated agricultural foodstuff as opposed to the wild gathered herb, the former the staff of life, the latter supposedly soporific. And the socio-political, with the sanctioned nuptial rite replacing illicit abduction and concubinage. And the religious, with the incorporation of the older chthonic deities into the Hellenized family of celestial Olympians. And both plants, in the pharmacopoeia of the midwife, the latter an abortifacient, the former an aid in parturition, inducing uterine contractions.

Cultivars, it was thought, are the product of human scientific intervention, without which they will revert to their poisonous inedible avatars. Sometimes, this is actually true. Thus the olive requires repeated pruning to prevent it from sending up a thicket of sprouts from its rootlets and returning to its fruitless natural state. The vine, too, needs pruning since it fruits only on new growth; and in ancient lore, its avatar was seen in the ivy, its sinister mimic, whose leaves and diminutive berries supposedly deranged the mind in their natural state, unlike the sophisticated intoxicant manufactured from the crushed grapes of the cultivar. An example from the New World is Indian corn, which if left unattended, drops its cobs of kernels to sprout all in the same spot, too close to grow without crowding each other out and becoming increasingly stunted like the original grasses from which it is hybridized. More to the point is the barley of the Eleusinian potion whose avatar was seen in the grassy weed that invades the tended plowland, the grain called tares, cockle, or darnel, *Lolium*, with the botanical epithet *temulentum*, 'drunken Lolium,' whose drunken toxicity derives from the ergot *Claviceps purpurea*, 'purple club-head,' descriptive of the enlarged deformed kernels formed by the dried sclerotia of the fungus, which spreads its poisonous contamination to the barley. In Greek, the weedy grass is named solely for these deformed kernels as *aira* or 'hammer.' The ergot itself was called 'rust' or *erysibe*, a metaphor that occurs also in English. As such, the botanic rust had its analogue in the destructive oxidization of iron that corrupts the metal utensils, returning them to the original ore. Demeter, the goddess of grains, could have the epithet Erysibe, for Greek deities often bear apotropaic names of their more sinister personae, just as Persephone is called the 'killer of Deadly Perse,' as the goddess who has displaced her more fearsome aspect as Perse.

It is only when we distance ourselves from the Eleusinian Mystery that we can expect to find mention of the ergot potion. Melampous, called 'black-foot' and the founder of a family of shamans, was a medicine-man, expert in understanding the speech of animals, birds, and insects, a gift he had received when two serpents licked his ears as he lay asleep. While attempting to win a herd of estrual cows as the bride price for the maiden Pero, named as the 'leathern food-pouch' like the *pera* in which was hidden some secret of the Eleusinian Mystery, Melampous was held prisoner by the 'Jailer' Phylakos, but he was able to gain his release by curing his captor's son of impotence. He learned from an old vulture, who had witnessed the event years ago, that Phylakos had inadvertently frightened his son when he approached him while gelding rams, bloody knife in hand. Phylakos had plunged the knife into an oak tree and gone to comfort the terrified child. It had lain there forgotten, rusting. Melampous scraped off he rust and administered it as a potion.

The symbolism of the rust is its mediation between primitivism and culture. From it can be extracted via alkaline hydrolysis, as we have seen, the visionary agent for the Eleusinian initiation. Pearlash or potash, called *tephra* and *spodos* in Greek, was known as an eye salve at least as early as Aristotle; and a century earlier, we know that the alkaline fluid called *konia* ('ash-water') was used for washing. There was also a *konia* derived from holy water and the ashes from sacrificial burnings that was used as a medicine. Hence, the procedure was within the expertise of the ancient pharmacologist, an art whose divine patroness was the third of the Eleusinian deities, Hekate. The Melampous myth also indicates a transition from human offerings to animal substitutes, for Iphiklos, the son of the Jailer, was probably not mistaken that the knife was originally intended for him and not the ram. Fiery immolation of human socalled volunteers and funeral pyres are frequent in the traditions of Eleusis. And in particular, Demeter, before teaching the Mystery, had laid the

Queen's son Demophoön, lulled to sleep with poppy juice, nightly in the hearth like a log to burn off his mortality, intending to make him celestial, like the daughter Persephone, whose contamination with flesh she had not yet come to accept. This event of the myth was commemorated each year at the Eleusinian rite by the 'boy from the hearth,' a child from a noble Athenian family whose initiation was funded at public expense. The secret agency of the potash would, therefore, not be without significance, as the mediation between body and soul, the reconciliation of chthonic and celestial realms.

As to when the potion was drunk, there are those who would imagine it prepared well in advance and perhaps sipped sometime while on route to the sanctuary on the day of the initiation; this view is intended to allow time for the barley-groats to ferment slightly, producing some kind of weak beer. If, however, it were prepared in advance and in the possession of the initiates, it could hardly be a secret; nor were the Greeks, who were never interested in beer, although they knew of it, likely to interpret a mild alcoholic intoxication as an entheogenic experience, especially since wine, in other circumstances, or more exactly, strong ancient Greek wine fortified with herbal inebriants, offered precisely that in the rites of the god Dionysos. The only supposed evidence for the mixing of the *kykeon* in advance is a papyrus fragment of a comedy of Eupolis where a foreigner is seen with barley-groats (*krimnon*) on his upper lip while still in Athens; the circumstances, however, are probably the affair of the Profanation of the Mysteries, which involved exactly this, the drinking of the *kykeon* illegally at home as a recreational inebriant, since certain well-placed Athenians with connections to the Eleusinian priesthood had apparently learned the secret of the potion. And indeed, Eupolis's foreigner is described as being overtaken by a hallucinatory fever (*epialos*, like a nightmare) while on the way to the marketplace because of the *kykeon* he had drunk.

The ten-day fast imposed upon the candidates for the initiation has also been called into evidence to help explain how some mild inebriant could have induced the visionary experience that by all testimony occurred at the Eleusinian sanctuary. This fasting, however, could hardly have been total, but just the avoidance of certain foods; and the offering of the mystic sacrificial pigs, washed in the sea, would certainly imply a day of feasting during this period of the fast. The vessel for mixing the *kykeon* was emblematic of the initiation ritual; both metal and ceramic exemplars still exist, the latter imitating in clay the style of the former. Ninnion's tablet depicts the procession that left Athens in the morning of the final day to walk the Sacred Road to the village of Eleusis. The women carry the vessel on their heads, with boughs of myrtle inserted in its handles: the symbolism of the myrtle indicates that the potion is a mediation, both as the rite of marriage, which will supplant the abduction of Persephone and unite the chthonic realm with the celestial and also as the redemption of Semele, since this is the plant with which Dionysos paid for his dead mother's resurrection. Appropriately, therefore, the initiates are led by Iakchos, who is Dionysos personified as the call that leads them into the netherworld. The potion, however, was not drunk from the *kykeon* vessel (nor is its style suitable for this purpose), but from cup-sized jugs, which the men in the procession carry in their hands. Each of the events along the way suggests that the Mystery procession was a mimesis of a journey to the otherworld, whose gateway awaited them in the Cave of Plouto beside the great Hall of Initiation at Eleusis. As they left the plain of Attica, the bridge over the River Kephisos and the ritual of the *gephyrismos* (or 'bridging') was practice for the narrow and dangerous passageway whose final locale would be the deep subterranean channel at the back of the Cave. Similarly, at the shallow saline lake called the Rheitoi or 'Streams' that marked the boundary of the Rarian plain in which lay the Eleusinian acropolis, the narrow bridge required that their carts be left behind and everything for the ceremony now be carried by hand. Here they were met by the hereditary priesthood of the Krokonidai, whose name suggests they are descended from the Athenian King Ion, Apollo's son via the *krokos* flower (supposedly the 'crocus') and after whom this month of Boëdromion ('Aid,' our September) was named for the alliance he made with Eleusis. The Krokonidai tied a 'string' or *kroke* to the right hand and left foot of each initiate, for such bows are emblematic of the joining between the realms. Their journey would be reversible, replacing earlier rites of human immolation. Hence, they had rested in Apollo's grove of laurel trees or *daphne* at the crest of Mount Aigeleos, before descending to the Rheitoi; and Artemis's temple lay still ahead of them at the entrance to the Eleusinian enclosure, beside the Well, the 'Well of Flowers,' the 'Virgin's Well,' where Demeter had rested when she first arrived at Eleusis, beyond whose watery surface at the base of the narrow shaft now resided her abducted daughter. (The grove of Apollo's entheogen, the temple of Artemis: because these were the two deities most implicated in the older rites of human sacrificial offerings.) There the initiates danced until nightfall, then passed with torches into the forbidden sanctuary, each accompanied by a sponsor, the mystagogue, up the incline, past the 'Laughless Rock,' which none would dare sit upon for fear of becoming stuck, like Theseus when he visited Persephone, and on into the

Hall or Telesterion of 'Completion,' such being the metaphor in Greek for what we call by the Latin of initiation or beginning.

Hall could accommodate perhaps only a thirtieth of that, they ranged themselves along the peripheral steps, sitting probably, not standing all packed together, and watched as the priestesses danced in the darkness with lanterns and incense burners on their heads. The Mystery Baskets or Cista Mystica were opened, whatever they contained hidden until now from profane view. Then the *kykeon* was mixed. Barley. Mint. Water. One of the Eleusinian priests called the Hydranos was specifically responsible for the water, for this would have to be prepared in advance, with its hydrolyzed visionary agent from the ergots that, we may surmise, had been specifically encouraged to grow by contaminating some portion of the crop with the 'honey dew' of *Claviceps purpurea*, the sweet exudation of its ascospores. "I have opened the basket; I have drunk the potion," was the final password. The unused portion of this special water figured in the rite, probably now just as the initiates prepared for their spiritual descent into the netherworld to encounter the Goddess. Two round urns on unstable bases where emptied, with the chant, no doubt repeated again and again by the whole congregation, *Hye kye*, "Rain conceive." After their descent, she would surface back up with them all, amidst a brilliant light, a fire that supposedly (although it may be just a metaphor) could be seen from miles away, as the Hierophant opened the door on the antique temple within the great Hall, at the moment of her giving birth to the Mystery child Brimos, who is otherwise known in the Eleusinian myth as Triptolemos, the prince to whom Demeter entrusted the Mystery and the sacrament of cultivating barley. Brimo, as Persephone now was called, had given birth to Brimos, a son named after her in the older matrilineal fashion: the 'Terrible Queen with her Terrible son.' This Queen is ultimately the reunion of the three phases of the goddess, as maiden, mother and crone, represented as Hekate, three women in one, and the patroness of witchcraft and herbalism; and the son similarly triform as the 'Triple Warrior' Triptolemos. With the conclusion of the Initiation, the winter rain would begin and the seed of Persephone would be hidden in the plowland to fruit again six months hence.

The mint in the potion, *Mentha pulegium* or pennyroyal, in addition to its symbolism as the wild antithesis to the cultivated barley, may have functioned merely to scent the drink, for without infusion in boiling water it would not be likely to release enough of its toxins - and it is specifically denoted as fresh mint; hence the potential abortifacient was surpassed by the superior magic of the ergot's birthing drug. It is possible, however, that the pennyroyal functioned in some way either to calm nausea (which is one of its uses in herbal pharmacology) or to potentiate or catalyze in some way the psychoactive toxins of the hydrolyzed ergot. This would require further experimentation to determine. Pennyroyal, commonly called fleabane and fleawort, also would have been noted for its apotropaic effect on flies; hence its botanic name of *pulegium*, from *pulex*, 'flea.' In concentration, the terpenoid ketone pulegone from pennyroyal is lethal for humans.

This greater Initiation was called the 'Vision,' the *epopteia*, something that even a blind man could see, as is testified by the votive of Eukrates, found in the excavation of the sanctuary, who without eyes saw, like everyone else, the Resurrection of Persephone. It was the culmination of the rite that had begun six months earlier in February, in the month of 'Flowering' called Anthesterion. That was the Lesser Mystery, so-called, the *myesis* or 'Closing of the Eyes' and being lulled to rest. It was the time to plant the other crop[1] that would fruit at the end of summer. If one observed the ground carefully at that time, the ergots from the winter crop, which readily detach from the ears of barley and which for centuries would be thought to be nothing more than sun-baked kernels amongst the healthy grains, display their other mode of propagation, as the mycelia of the sclerotia, like any other fungus, send up their fruiting bodies, the mushroom caps with their spore-bearing gills. It is as if these special kernels of barley had become the seed of the wild and seedless mushroom. This Mystery was the rite of death that was prelude to the resurrection. In myth, it was the Abduction of Persephone as she plucked a special flower that was called the *narkissos*, a word from the Minoan language that was assimilated into Greek and which is the root for our word 'narcotic.' Similarly, the place where she found the *narkissos* was called Nysa in the myth, a word that persists into modern Greek as nystazo, to 'get drowsy.'

It is unlikely that every initiate could attend the public part of this rite since the dangerous winter seas would not be navigable until at least a month later, although on occasion the rite was performed out of season to accommodate personages of importance. It is probable that versions of the ceremony were enacted in locale Eleusinian sanctuaries. Nor is it likely that the *narkissos* aspect of the fearsome rite was enacted by anyone more than just the titular Sacred Queen of the city of Athens, who experienced a *hierogamos* or 'Sacred Wedding' with the god Dionysos as some kind of maenadic ritual with her female attendants in the temple in the Swamps, also considered as a part of her house called the 'bull stall.' This was the transmutation of a ritual that went back to Minoan religion and had once required the offering of human victims. In Athens, some aspect of the rite was enacted at the so-called 'Hunting Preserve,' the mystery sanctuary of Agrai, on the banks of the River Ilissos, where as late as the mid-eighteenth century there still stood a temple of Artemis. In myth, it was remembered as the place where the nymph Oreithyia (or 'mountain ecstatic female') was abducted from her sisterhood of maidens called the 'drug-ladies' or Pharmakidai to establish Athens' own special family relationship with the world beneath the earth. These maidens were also known as the Hyakinthidai or 'hyacinth ladies,' in commemoration of the Hyakinthos whom Apollo 'unwillingly' (for such is always the ruse in human immolation) escorted to Paradise. Both the *narkissos* and the *hyakinthos* are flowers from the pre-Greek language, as is also the name of the river. In this essay, I summarize for the purpose of clarity and directness ethobotanical and metaphoric items that are documented in other writings (most recently, RUCK & STAPLES & HEINRICH 2000).

The *narkissos* flower figures prominently in Minoan art, on a sacrificial knife and wall paintings and a golden ring, probably the emblem of a shamanic priestess, depicting women as 'bee ladies' experiencing a vision, and even a ceramic plate showing a Persephone snake-goddess with her flower. We can identify it as *Pancratium maritimum*, the sea daffodil, of the amaryllis family. Its ethnopharmacological traditions (as well as its botanical family, which includes the toxic daffodil, whose poisons from the bulb can be absorbed through the skin, and the autumn crocus (*Colchicum* sps.), the latter associated with Medea and Prometheus) suggest psychotoxicity. Some fifteen species of amaryllis are toxic. *Pancratium trianthum*, because of its entheogenic properties is reputedly often found growing around shrines and sacred areas (EMBODEN 1979: 79, fig 44). It bears lily-like flowers of pink and white stripes on a naked scape. The bushmen of Dobe, Botswana, know this bulbous perennial as *kwashi*, a powerful sacred hallucinogen, capable of producing vivid and colorful visions. The bulb is not eaten, but rather it is slashed open and pressed onto self-inflicted wounds on the foreheads of participants. (One might compare the ritual flagellation of Spartan youths with squills.) The intoxicating principle is transported directly into the circulatory system, creating an immediate reaction. A related species is *Pancratium speciosum*, used by the Caribs of the West Indies under the name of *ognon* or *gli* as a powerful emetic. Some species are quite narcotic and are purported to have caused death by paralysis of the central nervous system; still others are classified as cardiac poisons. As always, ethnopharmacological expertise is essential for the ritual use of toxins.

The botanical name of *Pancratium* means the 'all-powerful,' like Christ as the Pankrator in Byzantine art, for its numinosity was assimilated in Christian mystery rites as the plant called *chreston*, an ancient corruption of Christ's name as the 'good' instead of the 'anointed' in Greek. It still goes by the name of the Virgin *Panaghia* in modern Greek. But somewhere along the way it also assumed the sanctity of the hoama or Soma which the Iranian Magoi used in their shamanic initiations, which is to say that it was assimilated to *Amanita muscaria*, the fly-agaric mushroom. This fungal sacrament persisted in Gnostic Christian sects, often labeled as heretical, most notably amongst the Manichaeans, whose rites, which thrived in the orient, were repeatedly reintroduced into western Europe by the Crusades. The role of flyagaric in Eleusinian lore can no longer be denied now that the plant elevated between the two goddesses, and apparently extracted from the Mystery wallet or *pera*, on the bas-relief from Pharsalia, Thessaly, in northern Greece, has been definitively identified as a large mushroom.

Fly-agaric in Greek mythopoeia is involved with the Gorgon Medusa and the hero Perseus, as well as the mooing of estrual cows and the purple-red heifer maiden Io, who is herself a female version of the same name as the Athenian king Ion, both with names that are cognate with 'violet,' a holy plant in Greek ethnobotany and involved with the linguistic root for 'drug,' as in the word for drug-man, *iatros*. This entheogen of the primordial times was hidden away from profane view, hidden until it was revealed on the night of the Great Initiation, within the rockrose, *kisthos*, after which the Cista Mystica or mystery hamper of the Eleusinian rite is named, a wild rose with single petals. Hence the prominence of rose motifs in the decoration of the sanctuary. Some claimed that it was the phallus of Dionysos that lay hidden within; others that it was a *kteis*; with either, it was emblematic of fly-agaric, a hermaphroditic phallus that penetrates its own vulva as it grows, like the Baubo creature who first served the potion to Demeter. The rose, itself, resembles the opium poppy flower, for that entheogen is well attested in Minoan religion; and after its assimilation to the Hellenized rite, it, too, enclosed the secret. The opium capsules, moreover, resemble little pomegranate fruits, another Eleusinian motif; one common weed in fields of grain is called the pomegranate poppy because of the likeness of its capsules. The pomegranate itself as it fruits on its tree resembles apples, like the golden apples of the

Hesperides, which one ancient vase painting identifies explicitly as mushrooms, for as the pomegranate hangs on its bough, the long calyx gives the red fruit a stipe like fly-agaric.

The fly-agaric is so named because of its attractiveness to flies, who seek out its toxins and were thought to be killed by it, although actually they revive after the experience. It would have been noted that the honey dew of the ergotized barley is similarly attractive to flies; it was long thought that it was just the sap of the grain exuded when the insects bore into the kernels. Fleabane, of course, represents the antithesis, repelling flies.

As for what the ordinary initiate could expect to experience at the *myesis*, we have only the traditions of the Purification. The rite is difficult to separate from the other aspects of the Anthesteria, which was a three-day wine festival (open to all and not restricted to the candidates for initiation) to which the ghosts of departed family members were invited. Orestes was said to have visited Athens during the festival, pursued by the netherworld sisterhood of Furies and the ghost of his mother Clytaemnestra, whom he had murdered, under orders from Apollo. He was exonerated and cured of his madness. Similarly, Herakles was purified of the murder of his wife and children. Anyone guilty of murder was offered the same ritual purification in preparation for the greater initiation; but certainly not many candidates could have been murderers.

Perhaps we get closer to the meaning with Melampous, the same shaman who discovered the rust potion. Another of his spectacular cures was the daughters of Proitos, the Proitidai. They had gone mad, becoming consubstantial with the fly-agaric (for such is the common experience of those who partake of the sacramental food): they grew bald with scabby patches on their skin, like the white fragments of the shattered universal veil adhering to the flyagaric's cap, and went mooing like cows in heat. Such estrual mooing was thought to be caused by the goading of the gad-fly or *oistros* (which gives us our word estrus) and which was also called the *myops*, 'squint-eye,' as in myopia, metaphorically appropriate for the myesis. He purified them at a temple of Artemis in Arcadia on the River Lousios. One of them died, but the other two he and his brother married, as replacements for Pero, the Mystery wallet, whom both of them had claimed as wife in the affair of the rust potion.

The purification of Herakles, Orestes, and the Proitidai is always depicted as involving the sacrifice of a pig, for the animal offering was the substitute for human immolation; while the candidate sat, head shrouded, enthroned, the *thronosis*, on the 'fleeceling of a ram,' which is another metaphor for fly-agaric. The ordinary initiate, however, probably began this indoctrination for the Greater Initiation simply by becoming at peace with the revenant spirits and by feasting on the slaughtered pigs - the pig offered in sacrifice as a token substitute for the death and myesis experienced by Persephone.

Footnote to Part 3

1. As would be expected, two crops were planted. The times of planting do not correspond exactly to the two Mysteries, which appear to be religious preliminaries for the actual plantings. Hesiod's *Works and Days* directs that the winter crop of Demeter's grain (presumably barley) should be planted when the voice of the migratory crane is first heard, *i.e.*, mid November (448), whether or not the rains have begun. The field should have been plowed in the spring and left fallow. If you wait for the winter solstice to plant, it is too late for the spring harvest. The winter crop should be planted when the cuckoo first calls, *i.e.*, March (486), if it has rained within three days as much as the height of an ox's hoof, which will assure a crop as good as the winter one. This crop is winnowed when Orion first rises at dawn, *i.e.*, July (587).

A Study of Cultural Bias in Field Guide Determinations of Mushroom Edibility Using the Iconic Mushroom, *Amanita muscaria*, as an Example. Mushroom field guides teach identification skills as well as provide information on the edible or toxic qualities of each species of wild mushroom. As such they function as modern-day village elders for an increasingly urban, nature-ignorant population. This paper identifies underlying cultural bias in the determination of mushroom edibility in English-language field guides, using the iconic mushroom, *Amanita muscaria*, as an example. We explore a selection of ethnographic and medical texts that report the use of *A. muscaria* as a food, and we accept parboiling as a safe method of detoxifying it for the dinner table. Mushroom field guides, however, almost universally label the mushroom as poisonous. We discuss the cultural underpinnings and literary form of mushroom field guides and demonstrate that they work within a mostly closed intellectual system that ironically shares many of the same limitations of cultural bias found in traditional folk cultures, but with the pretense of being modern and scientific.

Key Words: Edibility, field guides, mushrooms, *Amanita muscaria*, mushroom edibility, mushroom field guides, field guide bias.

Introduction

Modern-day field guides teach readers how to differentiate life forms; if they are field guides to mushrooms or plants, they frequently also provide information on edibility or other uses. In other words, they function in many ways as parent, grandparent, village herbalist, or shaman for people who do not live in a village or rural area and whose direct experience of nature is limited. Given the unprecedented wealth of information available to specialists in any field, it is tempting to assume that mushroom field guides have been good teachers. But have they? Without question they have been excellent teachers of taxonomy and identification skills. Mushroom morphology is described in detail using a specialized language, and field guides have more or less kept up with changes in nomenclature and advances in scholarship (most recently, molecular studies) from Linnaeus to the present, thereby enabling careful readers to identify many mushrooms successfully. With respect to edibility, however, the mushroom field guide literature has not kept up with advances in scholarship. The field guide literature tends to lack curiosity, to be resistant to change, and even to ignore facts that contradict the prevailing cultural consensus on a mushroom's edibility, as we will show.

Flora Londinensis (1777-1798), by English naturalist William Curtis, heavily influenced the development of the field guide genre. In fact, it should be considered one of its principal English-language prototypes. In this work, the author described the natural history and distinguishing characteristics of wild plants and mushrooms growing around London. Curtis (1777-1798) observed that:

> In some Countries, Mushrooms are made much more an object of food than with us... With us they are used more as an article of luxury

He also pointed out that most of the mushrooms sold in English markets were cultivated, and while he offered some information on the edibility of wild mushrooms, his overall message to readers was one of prudence:

> The best advice would be to caution persons in general, to meddle with no other sort than the common field Mushrooms...

Curtis was clearly aware that he was writing for an audience more comfortable eating cultivated mushrooms than wild ones, and therefore an audience that would be reassured by his extreme caution rather than disappointed or exasperated by it.

More than a century later, in North America, the cultural underpinning for mushroom field guide authors erring on the side of extreme caution remained the same. Louis Krieger, in *The Mushroom Handbook* (1936/1967 reprint: 113) wrote:

> The wild growing kinds [of mushrooms] are not of economic importance in this country, except with certain recent immigrants, chiefly from Russia and southern Europe. The average American of "Nordic" stock either does not care for mushrooms at all, or he stands in such mortal fear of the wild kinds that nothing could tempt him to eat one of these.

Despite significant changes in culinary culture over the past two centuries, fear of mushroom poisoning still runs as a leitmotif through English-language field guides, even those that explicitly seek to encourage consumption of wild mushrooms (e.g., Fischer and Bessette 1992; Schwab 2006; Kuo 2007).

We chose the well-known mushroom *Amanita muscaria* (L.) Lam. (or *A. muscaria* sensu lato - see Oda, Tanaka, and Tsuda 2004; Geml *et al*. 2006) as a convenient vehicle for exploring the nature of the edibility determination in English-language mushroom field guides because it has an extensive literature both inside and outside the field of mycology. Furthermore, it is so easily identified that its "poisonous" label cannot be attributed to authors trying to protect their readership from confusing it with more dangerous species.

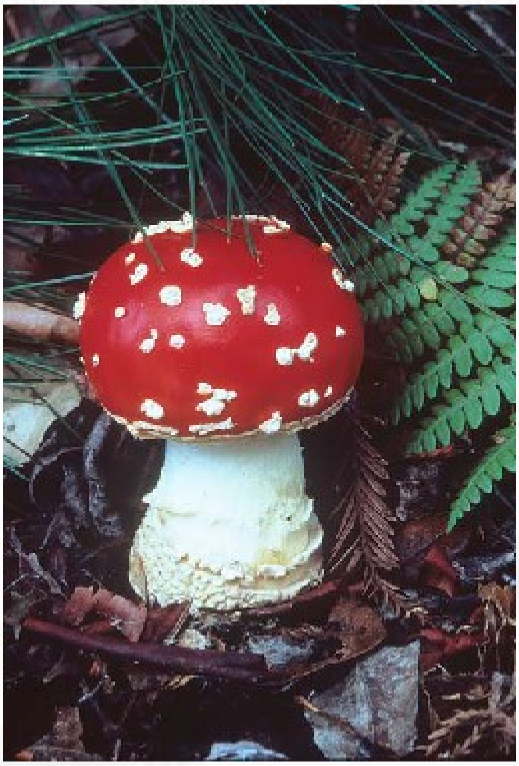

Fig. 1. The iconic *Amanita muscaria* is unmistakeable. (David Arora, all rights reserved).

The Fly Agaric: *Amanita muscaria*

Amanita muscaria is one of the easiest of all mushrooms to identify - the "red one with the white spots" (Fig. 1). As Letcher (2007) points out, "Even a child with no knowledge of natural history could identify one," as there are no other terrestrial life forms in the temperate zone with a similar color pattern. *A. muscaria* is also a cultural icon. It is widely depicted in cartoons and children's books, and is the mushroom that the dwarfs dance around in Disney's 1937 animated feature, *Snow White*. While most people are familiar with its caricature in commercial art, many are unaware that such a mushroom exists in nature. But it is, in fact, a common forest species in much of the north temperate zone and is widely naturalized in the southern hemisphere as well.

Most authors who write about *A. muscaria* remark on its striking appearance. The Scottish mycologist, Robert Greville (1823), called it the "most splendid chief of the agaricoid tribe," and the French naturalist Jean-Baptiste Lamarck, writing around the same time, elegantly expressed what so many feel when they come across it in the forest: "Cette espéce est remarquable par sa beauté" (Lamarck and Augustin 1815).

Amanita muscaria is known in most English-language field guides as the fly agaric or fly amanita. Steeped in milk, it has been widely used to attract flies; the flies become intoxicated by the infusion and then drown (Wasson and Wasson 1957:190; Michelot and Melendez-Howell 2003). But *A. muscaria* is also known as an inebriant. In parts of Siberia where alcohol was unknown, the recreational use of *A. muscaria* was well documented in the 18th century (e.g., von Strahlenberg 1736). Its modern use as an inebriant is also well known (Letcher 2007; Erowid 2008).

Ethnomycologist R. Gordon Wasson (1968) gained renown by focusing on its religious rather than recreational use, for example, by proposing that *A. muscaria* is the enigmatic Soma praised in ancient Vedic texts. His theories have gained currency in some circles but are still controversial (Letcher 2007). A standard dose as an inebriant is one to two caps (Greville 1823; Lincoff and Mitchel 1977); an upset stomach may or may not result. The active principle was long believed to be muscarine - isolated from *A. muscaria* in 1869 and the first mushroom toxin ever identified. Much later, however, it was demonstrated that muscarine, while found in a number of other mushrooms, occurs in such minute quantities in *A. muscaria* as to be clinically insignificant (Lincoff and Mitchel 1977; Benjamin 1995). It is ibotenic acid and muscimol (a more potent, decarboxylated version of ibotenic acid) that produce its inebriating effects (Takemoto *et al*. 1964; Bowden and Drysdale 1965;

Eugster *et al*. 1965). Both of the latter compounds are water soluble and, as we will show, can easily be removed from the mushroom by parboiling it and then discarding the liquid. It should be noted that we use the term "parboil" in this paper to mean precook by boiling, as per the third definition of Rombauer *et al*. (2006:1054). It should also be noted that the dangerously poisonous, amanitin-containing species, e.g., *A. phalloides* Secr., cannot be detoxified by any normal cooking or processing method, and are not discussed hereafter.

Despite being common, easy to identify, and an excellent savory mushroom after parboiling (Arora 2000; Rubel 2000), and despite a longstanding, albeit scattered, tradition of being eaten as a food in the European, Russian, North American, and Japanese countrysides, *A. muscaria* is almost universally characterized by modern mushroom field guides as being poisonous (e.g., Smith and Weber 1980; Lincoff 1981; Arora 1986; McKnight 1987; Hall *et al*. 2003; Miller and Miller 2006), even deadly (e.g., Groves 1962; Phillips 1991).

As we will show, 19th-century investigators from various disciplines established that the mushroom could easily be detoxified by parboiling it. This understanding was widely published in the 19th-century medical and toxicological literature but was ignored and decisively rejected by English-language mushroom field guide authors of the 19th and early 20th centuries. The rejection was so thorough that knowledge of *A. muscaria*'s food use appears to have effectively been lost by the late 20th century. Contemporary field guide authors continue to emphasize (and often exaggerate) the toxicity of *A. muscaria*, seldom mention that anyone eats it, and fail to provide precise and accurate instructions on how to detoxify it. As a result, *A. muscaria* is rarely picked for the dinner table except by those who inherit a local or family tradition of eating it.

The Toxicity of *Amanita muscaria*

English-language mushroom field guides agree that *Amanita muscaria* is poisonous and should not be eaten ("This is a dangerous fungus and should be avoided" - Miller 1972:32; see also McIlvaine and Macadam 1902; Marshall 1905; Güssow and Odell 1927; Smith 1975; Arora 1979; Lincoff 1981; Fergus and Fergus 2003; etc.). In many of these cited works, the authors mention the possibility of *A. muscaria* being fatal. Some authors even classify it as deadly (Gibson 1899; Krieger 1936), and the mushroom guide belonging to the prestigious Peterson Field Guide series (McKnight 1987) marks *A. muscaria* with the universally intimidating skull-and-crossbones symbol.

Yet in researching this article, we were unable to find a single adult death in North America indisputably caused by *A. muscaria*. Recent literature typically lumps poisoning by *A. muscaria* with poisoning by the closely related but significantly more toxic *A. pantherina* (DC.) Krombh. (Lincoff and Mitchell 1977; Benjamin 1995; Michelot and Melendez-Howell 2003). Furthermore, during the 19th and 20th centuries, atropine (the active principle of deadly nightshade, *Atropa belladonna* L.) was commonly prescribed as an antidote to *A. muscaria* poisoning in the mistaken belief that muscarine was the principal toxin. Atropine, however, may aggravate the symptoms of *A. muscaria* ingestion (Mitchel 1980). These variables complicate research into *A. muscaria* poisoning, but if *A. muscaria* has caused fatalities in North America, they have been few and far between. The only fatality cited by modern authors (Benjamin 1995:313) is that of Count de Vecchi, legate to the Italian Embassy in Washington, D.C., who allegedly died of *A. muscaria* poisoning in 1897 after dining on two dozen (!) mushrooms purchased in a local market (Prentiss 1898). Though his death has been linked repeatedly with *A. muscaria* (e.g., Jordan 1917:20), we use the word allegedly because it is impossible from the published accounts to reconstruct exactly what he died from; indeed, there is enough uncertainty to justify a separate article on the subject. The second most-often cited death by *A. muscaria* poisoning after that of Count de Vecchi is that of the Czar Alexis of Russia (e.g., Marshall 1905; Hard 1908) - in 1679! But authors do not agree on whether it was the Czar or the Czar's wife who was poisoned (Douglass 1917a).

A few mushrooms with histories of being eaten have been shown to be quite dangerous. *Gyromitra esculenta* (Pers.) Fr., for example, is popular in northern Europe but has caused deaths when not properly prepared, in part because there is a narrow dosage threshold between serious symptoms and a complete absence of them (Benjamin 1995). Another mushroom, *Paxillus involutus* (Batsch) Fr., has a history of being eaten in Europe but can cause severe allergic reactions in people who have eaten it for years. *A. muscaria*, however, does not have such a record, and an adult who eats one or two caps, even uncooked, does not, according to the literature, risk such severe consequences. The fatal human dose for *A. muscaria* has not been determined.

Benjamin (1995:309) speculated that 15 caps would be fatal, but it is unclear whether he was referring to *A. muscaria* or to the more toxic *A. pantherina*. Lincoff and Mitchel (1977) reported a man who ate 20 caps and survived, but also did not specify which species he ate. Many websites mention a fatality caused by the consumption of 20 or "two dozen" *A. muscaria* caps, but these apparently refer back to the unfortunate Count de Vecchi. What is known is that none of the hundreds, even thousands, of adults who have used *A. muscaria* as an intoxicant in North America have directly died from doing so (McDonald 1978:225), and early reports of *A. muscaria* usage as an inebriant in Siberia were not accompanied by references to fatalities.

Early Literature on the Edibility of *Amanita muscaria*

The documentation of historic *Amanita muscaria* food use is sparse, though persistent, and includes Europe, Asia, and North America. Most accounts merely mention its use as a food, but omit information on its safe detoxification. This dichotomy in the literature does not pertain only to *A. muscaria* or only to English-language field guides. See, for example, French mycologist Roget Heim's mention of the "poisonous" *Boletus satanas* Lenz being eaten by some people while failing to describe how "some people" detoxified the mushroom (Heim 1963:176).

The most explicit, widely-circulated, early account in English of *A. muscaria*'s use in the kitchen was by German physician and naturalist George Heinrich von Langsdorf, brought into the English-language literature as part of Robert Greville's influential presentation to the Wernarian Natural History Society in 1823. In Greville's (1823:344) translation: "[in Siberia it] is sometimes eaten fresh in soups and sauces, and then loses much of its intoxicating properties." While his translation might be construed to allow for the possibility of savory dishes that intoxicate slightly, it is more likely that the mushrooms were detoxified by being first parboiled, which would be consistent with the Russian method for detoxifying "poisonous" mushrooms described by Pallas (1794:76) from his visit to a region near Moscow. It is also consistent with our experience of current practice in Russia (as well as Lithuania), where many or most species of wild mushrooms are first boiled in water, drained, and then used as an ingredient in a dish.

While von Langsdorf's detailed descriptions of *A. muscaria*'s use as an inebriant in Siberia were subsequently cited (e.g., Christison 1829:653), his description of its use as a food was never cited again. But there were other mentions of kitchen use of *A. muscaria* - in, for example, Charles David Badham's (1863) book, *A treatise on the esculent funguses of England*. Its use as a food in Russia was noted in the Annals of Horticulture (1848:423), by Cooke (1880:211), and by William Delisle Hay (1887:154), who wrote, "The plant is eaten both in North Russia and in Southern France, *but of course* [emphasis ours] after being boiled and washed." These, plus more general references to "poisonous" mushrooms being eaten in the Russian and European countrysides (e.g., Pallas 1794; Porcher 1854; Whetstone 1898:263) formed a backdrop to the more precise work on *A. muscaria* detoxification published in the 19th-century medical and toxicological literature.

During the 19th century, efforts were made to prove in a methodical way that *A. muscaria*, as well as various other "poisonous" mushrooms, could be made safe for the dinner table. A French physician, Dr. Félix Archimède Pouchet, was especially influential in establishing the efficacy of boiling *A. muscaria* to remove its toxins, but he had a distinctly practical quest: he was looking for a way to unlock the nutrition tied up in wild mushrooms that the rural poor were not collecting because they thought them poisonous. In this quest to use "poisonous" mushrooms to help feed the poor, he was inspired by the root crop manioc (*Manihot esculenta* Crantz), described by one of his contemporaries (Taylor 1859:626) as follows:

> The root of one variety of this West Indian plant, known under the name Bitter Cassava, contains in its juice prussic [hydrocyanic] acid. It is, therefore, when recently expressed, highly poisonous, inducing coma, convulsions, and death… The vegetable principles of the plant, evaporated to dryness, form what is called *Cassava-cake*, which is not only inert, by reason [of] the poison being volatized, but highly nutritious. The starch obtained from this root is well known under the name *Tapioca*. Neither cassava nor tapioca yields any trace of prussic acid.

Pouchet (1839:323) explicitly acknowledged the example of manioc. As he put it (translated from the original French by the authors),

> Manioc forms the staple nourishment of a large number of people but has in its tissues the most

> violent of poisons; through skill, man extracts the poison from the nutritive part, and we think that science could do the same for mushrooms.

Pouchet's reference to manioc was a conceptual breakthrough. In suggesting that the French eat *A. muscaria*, he did not argue that it was a traditional food someplace else, like in Italy or Russia, but simply that through scientific methods he had determined it could easily be rendered safe to eat. He was also saying that mushrooms could be thought of in the same way we think of other foods that are edible, and that by analogy what he was doing to *A. muscaria* was no more extreme than detoxifying manioc.

One of Pouchet's experiments was to boil five *A. muscaria* caps per liter of water for 15 minutes. He strained out the mushrooms and fed the broth to dogs, who died, thus demonstrating that the toxins were water soluble. But he also fed dogs boiled caps without the broth, and they thrived, thus demonstrating that the caps were no longer poisonous. (Note: smaller dogs are cheaper to maintain for experimental purposes than large ones, so we can infer that five caps for one of Pouchet's dogs is equivalent to 20 or more caps for a human adult.)

Pouchet's experiments were widely described. Reese (1874:346) said in his manual on toxicology, "A third [dog] which was fed [by Pouchet] on boiled amanitas for two months actually fattened on this food." Pouchet's experiments were also cited in the standard medical references of that era, for example in *Medical Jurisprudence* (Wharton *et al*. 1860:569; Wharton *et al*. 1873:470; Wharton and Stillé 1882:675). In all of the above cases, the edibility of parboiled *A. muscaria* was accepted as fact.

While Pouchet, to demonstrate edibility, experimented on animals, another Frenchman, M. Gerard, experimented on himself, and on his family. In 1851, Gerard demonstrated that *A. muscaria*, along with a number of other "poisonous" mushrooms, could be safely eaten if parboiled (Gerard 1852). He was also widely cited in the 19th-century toxicological literature. Here is Gerard's recipe for *A. muscaria* as translated by the Southern Society for Clinical Investigation (1853: 261):

> To every five hundred grams of mushrooms cut up into a medium size, a liter of water, slightly acidulated by two or three spoonfuls of vinegar (or, if nothing else is on hand, gray salt), should be used. If [only] water alone can be obtained, this must be renewed once or twice. In this fluid the fungi are to be macerated for two entire hours, after which they are to be washed in an abundance of water. Next, they are to be put into cold water and boiled for half an hour, after which they may be taken out, washed, dried, and used as food.

Interest in Gerard's work was so great that it was republished a decade later, again in English, under the title, "A simple means of removing the poisonous properties of suspicious mushrooms" (Gerard 1863), and it was cited in Hay's (1887) book on British mushrooms. It is worth noting Gerard's use of vinegar. This use may be traceable to Jean Jacques Paulet, a French botanist and mycologist who was credited with demonstrating in 1776 that "the mode in which... [mushrooms] were cooked" affected toxicity, and that salt and vinegar were particularly helpful in this regard (Lindley 1836:422).

The belief in the edibility of parboiled *A. muscaria* was apparently not a controversial one in the 19th-century American medical community. Dr. Francis Porcher cited most of the above sources (including Pouchet) in his report to the American Medical Association entitled *The Medical, Poisonous, and Dietetic Properties of the Cryptogamic Plants of the United States* (Porcher 1854). He also cited several sources as saying of *A. muscaria* that, "in the middle of France they had constantly been in the habit of eating them" (Porcher 1854:61). Of the ethnographic literature in general, he concluded that what was written was really true: that many poisonous mushrooms could be rendered edible through knowledgeable processing. In his own words, "There is no reason to doubt the fact that sorts *justly esteemed poisonous are really used* [author's emphasis]" (Porcher 1854:47). Porcher's work, with its imprimatur of the American Medical Association, was also cited in the aforementioned and influential *Medical Jurisprudence* (Wharton *et al*. 1860; Wharton *et al*. 1873; Wharton and Stillé 1882).

At the end of the 19th century, the noted American botanist, Charles Peck (1895:214), in an extensive passage on the use of *A. muscaria* as a food, described Americans who detoxified *A. muscaria* with vinegar and/or water. But the most detailed, objective, and accurate description of its edibility was written in 1898 by

Frederick Vernon Coville, a distinguished botanist, explorer, and ethnographer, who authored 170 books and articles (but who, significantly, was not a mushroom field guide author). Coville was the first to discover the importance of soil acidity to blueberries; he also wrote books on desert plants, served as Chief Botanist for the United States Department of Agriculture and as Chairman of the National Geographic Society Research Committee, and was the first director of the United States National Arboretum. Coville published a report on *Amanita muscaria* in 1898 for the United States Department of Agriculture as part of an investigation into the death by mushroom poisoning of Count de Vecchi of Washington, D.C. In this work, entitled *Observations on Recent Cases of Mushroom Poisoning in the District of Columbia*, Coville exhibited a reasonably solid grasp of the scientific understanding of the edibility of *A. muscaria*. He went to the market where the Count had purchased the mushrooms that allegedly poisoned him and, remarkably, discovered *A. muscaria* being eaten in Washington, D.C.!

> It is well known that in some parts of Europe the fly amanita, after the removal of the poison by treatment with vinegar, is a common article of food. It was interesting to discover not long since that among some of our own people the practice prevails. Though most of the colored women of the markets look upon the species with horror, one of them recited in detail how she was in the habit of cooking it. She prepared the stem by scraping, the cap by removing the gills and peeling the upper surface. Thus dressed the mushrooms were first boiled in salt and water, and afterwards steeped in vinegar. They were then washed in clear water, cooked in gravy like ordinary mushrooms, and served with beefsteak. This is an exceedingly interesting operation from the fact that although its author was wholly ignorant of the chemistry of mushroom poisons, she had nevertheless been employing a process for the removal of these poisons which was scientifically correct. (Coville 1898: 19)

Coville's work stands as a model for writers today. While Coville was not a mushroom expert, he reviewed the scientific literature, the ethnographic literature, and did his own field work. Although he did not go on to recommend that his readers eat *A. muscaria*, he used his understanding of mushroom toxicology to explain the findings of his field research and to reconcile the two. He unambiguously concluded that "after the two treatments the mushroom is free from poisons." Thus he is notable for using the science of his day to explain why a folk method of detoxification was effective.

20th-Century Literature on the Edibility of Amanita muscaria

Since contemporary mushroom field guides teach that *A. muscaria* is poisonous, even potentially deadly, it is difficult to appreciate the extent to which the 19th-century toxicological literature was united behind the ethnographic literature in declaring that *A. muscaria* is edible after parboiling. Knowledge, particularly in written form, is widely assumed to progress over time as more and more bits of information are accumulated, examined, and tested. In the case of *A. muscaria*, however, 20th-century mushroom field guides have proved strangely impervious to the facts, as we will show, and knowledge of its edibility seems actually to have regressed.

Coville's work was cited in the early 20thcentury medical literature (e.g., Wiley 1917:445). Furthermore, a medical doctor, Beaman Douglass (1917b:212), reported that, "The negroes of the southern states are said to have learned empirically how to prepare [*A. muscaria*, as well as *Russula emetica* (Sch.) Pers.] which they eat freely." The field guide literature, however, did not follow up on Coville (despite his excellent reputation) and the other explicit 19th-century literature on *A. muscaria* edibility. Instead, the field guide literature rejected its edibility and closed ranks around its toxicity.

In an act of omission for the apparent purpose of distorting or suppressing evidence of its edibility, Nina Marshall, in *The Mushroom Book* (1905:49-50), cited Coville but failed to say that *A. muscaria* was eaten in Washington D.C., and that there was a "scientifically correct" way to detoxify the mushroom. Instead, she labeled *A. muscaria* "poisonous," and emphasized its danger by stating, "It is known to have caused much sickness and many deaths. It caused the death of the Czar Alexis of Russia, and of the Count de Vecchi in Washington." While she did mention that *A. muscaria* is "cooked and eaten by the Russians," she prefaced that statement with the phrase "it is said" (rather than "it is known"), thus implying that it may not be true. Her respected contemporary, Prof. George F. Atkinson of Cornell University, said of *A. muscaria* in his field guide

(Atkinson 1900), "... deadly as ordinarily found, [but] is undoubtedly used quite largely as food in parts of France and Russia, and it has been eaten repeatedly in certain localities in this country without harm." But Atkinson, unlike Coville, did not explain in which localities in the United States *A. muscaria* was eaten, nor how such a "deadly" mushroom could be safely prepared.

The most influential North American mushroom field guide of that era, however, was *One Thousand American Fungi* by Captain Charles McIlvaine (McIlvaine and Macadam 1902), a book that is still in print. McIlvaine was interested in the science of his day, but he proudly broke with the tradition of field guide authors simply following each other's lead, and sought to establish edibility on a sound personal and scientific basis. He tested hundreds of mushrooms on himself, including some routinely characterized as poisonous, and even had a group of designated "undertasters" (McIlvaine and Macadam 1902/1967 reprint: xv, 454).

Uncharacteristically, however, McIlvaine exaggerated the toxicity of *A. muscaria*, a mushroom that he asserted was "undoubtedly poisonous [author's emphasis] to a high degree" (McIlvaine and Macadam 1902/1967 reprint: 15). McIlvaine claimed to have become intoxicated from eating a hazelnut-sized piece of raw cap - an impossibility according to Phipps (2000), unless the effects were psychosomatic; that McIlvaine experienced an anxiety reaction is also suggested by the fact that he counteracted the mushroom's effects by smoking a pipe! McIlvaine emphatically rejected the use of vinegar, or any other method, for extracting poison from the mushroom on the grounds that one couldn't be sure it had all been removed. His mention of the use of vinegar (McIlvaine and Macadam 1902/1967 reprint: 15-16) implies that he was familiar with Coville's "scientifically correct" method for detoxifying *A. muscaria*. His rejection of the detoxification procedure was subsequently cited by others as a reason to reject it (e.g., Benedict 1908:94).

Why didn't McIlvaine test detoxification procedures prior to rejecting them? The answer seems to be his personal bias, for he was no stranger to conducting experiments to prove a point. McIlvaine injected etherized cats with *A. muscaria* juice, killing them. This inspired a physiologist, William Carter (1901), to conduct a bigger study of the effect of injecting a range of animals - cats, dogs, rabbits, even frogs - with *A. muscaria* juice. These experiments, unlike those of Pouchet, had no chance of demonstrating that the mushroom was edible. With the hindsight of one hundred years, it is evident that McIlvaine and Carter presaged a 20th-century shift toward using increasingly sophisticated laboratory techniques to study toxins and toxicity while abandoning Pouchet's quest to use science as a means of learning how to safely detoxify mushrooms for the table.

The first comprehensive academic treatment of North American agarics was written by Prof. Charles Henry Kauffman (1918). Kauffman gave a detailed morphological description of *Amanita muscaria* in which he called it "deadly poisonous," saying, "It is a delightful object for the artistic eye of the nature lover but in all other respects a menace." Yet buried in the appendix of this same field guide (Kauffman 1918; 1971 reprint: 841-842) is a section called "Treatment of *Amanita muscaria* poisoning," written by Dr. O. E. Fischer, who, significantly, was not a mycologist but a medical doctor, like Porcher and Douglass. Fischer cited *A. muscaria* as being eaten as food in Saxony and Bohemia. He also cited Coville, and gave the African-American market woman's recipe for its safe preparation.

Writing ten years later, William Sturgis Thomas, president of the New York Mycological Society and author of the mushroom volume (Thomas 1928) in Putnam's Nature Field Books series, based most of his mushroom edibility information on Peck. Incredibly, however, he skipped over the information that Peck (1895) provided on the use of *A. muscaria* as food, just as Marshall had purposefully dropped Coville's authoritative information on its detoxification.

The next important field guide mention of *A. muscaria* being eaten was in *The Mushroom Handbook* (1936), by Louis Krieger. A mycological bibliographer, Krieger was conversant in English, French, and German, and his knowledge of the relevant literature was second to none. Perhaps reflecting the prevailing climate of hostility toward drugs (the notorious anti-drug movie, *Reefer Madness*, was also released in 1936), Krieger chose to exaggerate the intoxicating effects of raw *A. muscaria* by describing, apparently without basis, Siberian villages full of "intoxicated people running amok with drawn knives and false courage endanger[ing] the lives of their fellows." Regarding the edibility of *A. muscaria*, Krieger stated, "This species, though known to be deadly, is eaten without ill effects by some people." He provided no specific information on who ate *A. muscaria* nor did he give any details for safely preparing it.

But no major field guide author so fully embodies the dichotomy between the careful and scholarly treatment of mushroom taxonomy and the idiosyncratic treatment of mushroom edibility as Alexander Smith, the preeminent North American mushroom taxonomist of the 20th century. Smith authored approximately 200 articles and books over a long and distinguished career and named many new species. He dedicated his first field guide for the general public, *Mushrooms in Their Natural Habitats* (Smith 1948), to his mentor, the aforementioned Charles Kauffman, and labeled *A. muscaria* as poisonous, thus following Kauffman (1918) as well as Gibson (1899), McIlvaine and Macadam (1902), Marshall (1905), and Krieger (1936), among others, in rejecting or ignoring the 19thcentury toxicological and ethnographic literature. Like Gibson (1899), Smith attributed stories of people safely eating *A. muscaria* to misidentification. He even speculated that the people were probably eating *A. frostiana* Peck, a North American species unknown in Europe and Asia. Smith's next work for the general public was *A Mushroom Hunter*'s *Field Guide* (1958, 1963), a book that sold 100,000 copies and was hailed as the "first modern [mushroom] field guide for amateurs" (Thiers 1987). In the first version of this book, Smith (1958:136) said this of *A. muscaria*:

> Poisonous. If someone claims to know how to cook it so that it is edible, do not argue with him, but do not eat any. Apparently there are ways of extracting the poison, but the risk is not worth the effort.

It is unclear to us what Smith's reasons were for saying not to argue the point (because it truly is edible?), or what the "effort" is that he refers to. But in the second "revised and enlarged" version of the same book, Smith (1963:177) labeled *A. muscaria* "poisonous," and then immediately went on to say,

> However, some people extract the poison and then eat the mushroom, apparently with no ill effects. They claim it is a most delicious species. The instructions, as I have heard them, are to parboil the specimens in salt water until no more yellow scum comes to the surface...

As we can find no other specific mention in the mushroom literature of "yellow scum," we conclude that Smith was in touch with credible informants who regularly ate *A. muscaria* and considered it delicious. But he provided no information about who these people were, and, unlike Coville, he didn't stand behind his own ethnographic report. Instead, he went on to tell readers that if they tried the detoxification method he had just described, that they did so at their own risk (Smith 1963:177). Smith's distrust of his own finding suggests that he was unaware of the substantial body of l9th-century literature on the subject, and furthermore, that this body of knowledge regarding *A. muscaria*'s edibility had already effectively vanished. Furthermore, Smith seems to have made no personal effort to verify the efficacy of parboiling *A. muscaria*, an indication of his and his culture's lack of interest in wild mushrooms as food. Thus he was clearly working within the same intellectual framework as the 18th-century English field guide author William Curtis, one in which the accuracy of the edibility information is not as important as that of the taxonomic information.

In Smith's 1975 work, *A Field Guide to Western Mushrooms*, under the description of *A. muscaria*, he reverted to labeling it poisonous and dropped the reference to detoxification (Smith 1975:167). However, as in Kauffman (1918), there is completely different information buried in the chapter on mushroom poisoning, namely, the unambiguous statement "People who know how to boil the poison out of it use it as an esculent" (Smith 1975:15). Five years later, in the revised edition of *The Mushroom Hunter*'s *Field Guide* (Smith and Weber 1980:171-172), Smith once again changed his position, or at least his emphasis. Instead of continuing to characterize *A. muscaria* as "poisonous," he broke with his own past as well as with the entire history of mushroom field guides by labeling it as "poisonous to most people," thus implying that some people are immune to its toxins and can eat it with impunity. Smith then went on to say that "some people can eat this species and suffer no ill effects; others parboil the specimens and discard the liquid..."

While specimens of *A. muscaria* vary in the amounts of toxins they contain (Benedict 1972), and while individuals may vary in their sensitivity to the toxins, there is no literature to support the idea that anyone is immune to its toxins and could eat as many non-detoxified specimens as they wanted without becoming intoxicated or nauseous or worse. Smith cited no references for his extraordinary claim that non-detoxified *A. muscaria* is edible for some people, but the phrase "some people can eat this species and suffer no ill effects" is almost verbatim from Krieger (1936/ 1967 reprint: 238-239).

Despite his inconsistencies, his apparent distrust of his own findings, and his failure to use science to support (or debunk) folk detoxification techniques, Smith deserves credit for breaking with his 20th-century predecessors in publishing accounts of *A. muscaria*'s usage as food. Smith was a mushroom taxonomist, not an ethnographer, and he did not often report ethnographic uses of mushrooms in his books. He clearly did not trust the detoxification procedure he described for *A. muscaria*, and strongly recommended against employing it. Yet, in four books spanning more than 20 years he repeatedly described or alluded to this same detoxification procedure which he distrusted. Why would he do so when it would have been so much easier not to mention it being eaten and simply to agree with the 20th-century field guide consensus that *A. muscaria* was poisonous? We think his repeated references to detoxification point to food use of *A. muscaria* in North America consisting not of isolated instances, but of a tradition sufficiently developed and widespread enough that Smith anticipated some of his readers encountering it, and thus felt compelled to inform them of it.

Though Smith was a highly respected mushroom expert, his repeated references to the use of *A. muscaria* as an esculent were ignored by subsequent field guide authors (e.g., McKenny and Stuntz 1971; Miller 1972; Guild 1977; Arora 1979, 1986; Lincoff 1981; Fischer and Bessette 1992; Jordan and Wheeler 1995; Bessette *et al*. 1997), suggesting a broad cultural bias against taking ethnographic references to mushroom food use seriously when they contradict prevailing practices. However, we find Smith's allusions tantalizing.

In addition to the aforementioned references by Peck, and more specifically to the food use of *A. muscaria* by African-Americans in America's South, we surmise that there was, and may still be, an undocumented tradition of eating *A. muscaria* in North America. Besides Smith, who collected mushrooms extensively in the Pacific Northwest and Midwest, Chilton (in Rumack and Salzman 1978:112) mentioned a "few people in Europe and North America" preparing *A. muscaria* for the table. He described a procedure similar to that of Coville's African-American market woman, though without the final soaking in vinegar. Lincoff and Mitchel (1977:85) mentioned unconfirmed reports from the Pacific Northwest of people who "eat the Fly Agaric as a food after peeling the cap, parboiling the peeled mushrooms, discarding the cooking water, and recooking them," but, like so many 20th-century authors, they warned against doing so. Denis Benjamin (pers. comm.) reports similar usage of *A. muscaria* in the Pacific Northwest during the 1980s, with one man telling him that his family had been eating *A. muscaria* as food for three generations.

We have also encountered people who eat *A. muscaria* as food, both in Europe and North America. One such person, a man living in the Sierra Nevada foothills of California, actually came to doubt the safety of his family's tradition of eating parboiled *A. muscaria* based on what he had read in Arora's (1986) field guide. The man asked Arora if there were any long-term ill effects from dining on parboiled *A. muscaria* because he hadn't noticed any short-term ill effects. It is difficult to imagine rural Tibetans or Mayans who had been taught by their parents how to safely prepare a particular mushroom losing confidence because of what was written in a book. But in 20th-century North America, the prestige of the written word was such that this rural man sought assurance for something that he had been doing all his life, and he ironically sought it from a field guide author who had never (at that time) eaten it as a food, and, unaware of the 19th-century understanding that it was edible, had merely repeated the 20th-century consensus that it wasn't. As a result of this encounter and further research with Alan Phipps in Sanada, Japan, where *A. muscaria* is an esteemed edible mushroom (Wasson and Wasson 1957; Arora 2000; Phipps 2000), Arora has changed his assessment of the edibility of *A. muscaria* and now considers it to be a delicious edible mushroom if parboiled. This information, however, has not yet made its way into his field guides (Arora 1986, 1991).

The only modern English-language field guide we have found that categorically states that one can make *A. muscaria* safe to eat is *The Mushroom Manual* by Lorentz Pearson (1987). Citing the Swedish field guide author Bengt Cortin, who personally tested more than 300 species of wild mushrooms including many of doubtful edibility, Pearson (1987:61) offered the following detoxification method:

> To render *Amanita muscaria* safe to eat: (1) carefully peel the cap, removing every bit of the pellis or rind...; (2) cut into relatively small bits; (3) place the bits in boiling water and boil for exactly five minutes; (4) discard the water, and boil again in fresh, boiling water for an additional five minutes; (5) discard the water and prepare the mushroom in the usual way.

Paradoxically, however, just as references to *A. muscaria* food use were buried in chapters on poisoning in Kauffman (1918) and Smith (1975), the above recipe was placed in a chapter ominously titled "The Fatal Five," thereby severely undercutting its impact. As we have already noted, other English-language field guide authors have not followed up on Smith's description of *A. muscaria*'s edibility, nor on Pearson's rendition of Cortin's precise instructions.

By the end of the 20st century, mention of the use of parboiled *A. muscaria* as a food had been practically expunged from the written record. Kenneth Lampe (1979:95), in a pharmacological review of toxic mushrooms, stated, "Cooking does not markedly affect [its] activity," and Didier Michelot and Leda Maria MelendezHowell (2003), two scientists favorably disposed towards *A. muscaria*, wrote in an otherwise wellresearched paper that"Contrary to some statements, cooking does not notably lower toxicity, demonstrating that the active components are not heat sensitive." Michelot and Melendez-Howell wanted to show that the mushroom could be detoxified and then eaten for dinner, but the late 20th-century literature that they worked with no longer included the 19th-century knowledge that the toxins in *A. muscaria* are water soluble. Thus they didn't realize that "cooking" per se, i.e., the application of heat, does not detoxify *A. muscaria*, but that boiling it in water does. Their failure to match the correct cooking method to the mushroom testifies to a more general failure on the part of the literature (and especially mushroom field guides) to be more accurate and explicit in reporting the well-established fact that *A. muscaria*'s toxins are water soluble.

Recent Food Use of *Amanita muscaria* outside North America

This work focuses on English-language field guides. A methodical survey of mushroom field guides from Europe and Asia would be instructive. As an example of what one is likely to find, the Swedish author Bengt Cortin (1942) wrote (translated by Eric Danell), "Nowadays it has been determined, that this poisonous mushroom is harmless if treated in the right way." The literature that supports that statement would be well worth knowing. An Italian author, Bruno Cetto (1994) mentioned *A. muscaria* being eaten as a food in contemporary Italy. Lucius von Frieden (1964) also mentioned it being eaten in Europe. But neither author provided concrete details, and both focused on the broader national attitude towards *A. muscaria* rather than on regional practices that deviated from the norm. Even so, the mention of *A. muscaria* use as food in parts of Italy suggests that a broader survey of field guides might uncover useful information on the practice of *A. muscaria* consumption in Europe that could then be used to focus field research where one is most likely to still be able to find people who can explain how they detoxify the mushroom, what they do with it, and how it fits into their culture and cuisine.

The best English-language report on the current use of *A. muscaria* as food in Asia, or for that matter, anywhere, is Phipps' (2000) treatise focused on the town of Sanada in Nagano Prefecture, Japan. Phipps' primary goal was to ascertain through laboratory testing whether the traditional salting method there rendered *A. muscaria* totally safe. It did. After boiling and storing the mushrooms in salt - the predominant treatment of *A. muscaria* in and around Sanada - Phipps found that there was no detectable muscimol or ibotenic acid. Phipps documented two other preparation methods: grilling and drying. The grilled caps are typically eaten by groups of men along with *sake*, while the dried caps are powdered for use as a flavor-enhancing condiment, producing the taste sensation the Japanese call *umami* (Kawai *et al*. 2002); according to Lincoff and Mitchel (1977), ibotenic acid and muscimol are far more powerful than the better known *umami* agent, MSG. In contrast to parboiling, Phipps found that both grilling and drying, far from detoxifying the mushroom, convert some of the ibotenic acid into the much more potent compound, muscimol (Phipps 2000:52-58). Phipps' work offers a model for combining ethnographic research with laboratory science to clarify the role of basic culinary processes - drying, grilling, roasting, frying, boiling - in eliminating or concentrating mushroom toxins.

Amanita muscaria: A Special Mushroom but Not a Special Case

The consistent labeling of *A. muscaria* as poisonous and the failure of modern field guides to acknowledge its use as food is by no means a special case. Many other mushrooms that can be made edible through *knowledgeable* processing are routinely dismissed as "poisonous" or not edible in mushroom field guides, whether out of bias, ignorance, or both. For example, *B. luridus* Schaeff., *B. erythropus* sensu auct. mult., and their close relatives are commonly eaten in China and Europe (especially Italy) but are labeled poisonous by many English-language field guides (e.g., Miller 1972; Bessette and Sundberg 1987; Bessette *et al*. 1997; Hall et. al 2003). *B. satanas* Lenz is eaten in Sicily after a complex cooking process (Galli 1996) but is described as poisonous by most field guides, including Italian ones (e.g., Cetto 1994; Testi 1995; Papetti *et al*. 1999). *B.*

subvelutipes Peck is eaten in Japan (Imazeki *et al*. 1988) and has been safely served for years by restaurants in Massachusetts but is listed as poisonous in field guides written specifically for that area (Bessette *et al*. 1997; Bessette *et al*. 2001). *Gomphus floccosus* (Schwein.) Singer is often listed as poisonous (e.g., Miller and Miller 2006), but is commonly sold in the markets of Mexico and China. Acrid, red-capped russulas such as *Russula emetica* are widely eaten after being cooked or salted but are labeled poisonous by field guides in many languages (e.g., Hagara 1987; States 1990; Kuo 2007). Various peppery species of *Lactarius* such as *L. torminosus* (Schaeff.) Gray are condemned as poisonous by assorted English-language field guides (e.g., Glick 1979; Phillips 1981, 1991; McKenny *et al*. 1987; Miller and Miller 2006) but form an important part of northern European, Russian, and Siberian cuisine, as noted by Heilmann-Clausen *et al*. (1998: 30) in their monograph on *Lactarius*:

> *Lactarius torminosus* is listed among the poisonous species in southern Europe, but in Finland the edibility of the species is not questioned.

Not only individual species but entire genera are routinely dismissed by field guides as poisonous or inedible or worthless (e.g., Lincoff 1981; Arora 1986; Jordan and Wheeler 1995), despite containing commercially-valuable edible species with long histories of usage. These genera include *Astraeus, Calostoma, Cortinarius, Entoloma, Hebeloma, Helvella, Schizophyllum, Scleroderma, Suillus*, and *Tremella*, to name just a few.

Criteria for Edibility Determinations of Mushrooms versus Plants

Listing *A. muscaria* as edible rather than poisonous is a completely unremarkable judgment in a culinary context, or even in the context of most books on plant identification and uses. In many cases, the processing required for traditional plant foods is far more exacting and labor-intensive than the parboiling required to make *A. muscaria* edible. For example, most bamboo shoots (e.g., *Dendrocalamus*, *Phyllostachys*, and *Bambusa* spp.) require boiling, in some cases with two changes of water. Researchers have determined that the traditional parboiling method for preparing the seaweed *hijiki*, *Hizikia fusiforme* (Harvey) Okamura, removes potentially dangerous quantities of arsenic found in the raw product (Hanaoka *et al*. 2001; Ichikawa *et al*. 2006). Lupine or wolfbean (*Lupinis albus* L.), which the authors recently purchased at a California supermarket, may require up to four *days* of soaking and water changes to make it safe for the table (Grande *et al*. 2004). The Canadian Food Inspection Agency (2005) recommends detoxifying fiddlehead ferns (*Matteuccia struthiopteris* L.) prior to "sauteeing, frying, or baking" by rinsing them in several changes of water, and then boiling for 15 minutes, or steaming for 12 minutes. Pokeweed (*Phytolacca americana* L.), the subject of a popular radio song in 1965 and a frequently eaten wild food in the American South and Midwest, has roots that can be fatally poisonous and shoots that are "one of the best tasting vegetables on the planet" (Brill 2002); the shoots, however, need to be boiled *three* times (and the water discarded) to render them safe to eat (Brill 2002:164-165). We have already mentioned that cassava, the source of tapioca, requires special treatment to eliminate hydrocyanic acid (Taylor 1859). Another staple, taro (*Colocasia esculenta* [L.] Schott), must be cooked 10-45 minutes depending on the variety and the part of the plant used in order to avoid experiencing "the sensation of a hundred red hot needles" in one's throat (Solomon and Solomon 1998:375).

As can be seen, this list of examples ranges from relatively obscure dietary supplements to widely-used, culturally-salient staples, and the consequences of improper preparation can be milder than for *A. muscaria*, or more severe. Yet all of these foods are consistently described in plant field guides (as well as cookbooks) as being edible, and it is either taken for granted that readers know how to prepare them (the packet of lupine we purchased had no instructions for its preparation!), or else directions for their processing are provided. Their toxicity, while acknowledged, is not used to dissuade people from eating them, but is instead treated as an inconvenience - something to be removed as one would remove dirt from a garden carrot. Jacquat and Bertossa (1990), for example, said this about the Thai plant *phak naam* (*Lasia spinosa* Thw.): "The young leaves are edible, but must be cooked or fermented to neutralize the hydrocyanic acid." While mushroom field guides are not cookbooks, and cannot be expected to carry the burden of an encyclopedic record of mushroom use, it would be easy enough for authors to say something equally terse, *useful*, and non-inflammatory about *A. muscaria*, such as, "edible if sliced thinly and parboiled in a large pot of salted water for 15 minutes, rinsed, and the water thrown out." They are, after all, the authorities that most urban people (including many scientists) consult first when they want to learn about a mushroom.

Contemporary English-language cookbook and plant field-guide authors operate in the same litigious climate as mushroom field guide authors, and all write for increasingly nature-alienated, rather than nature-immersed, audiences. But the formers' emphasis tends to be on a plant's edibility, not its toxicity, at least where there is a history of usage, while wild mushrooms appear to be held to an entirely different standard of accountability by English-language field guides.

It is tempting to attribute this double standard to the entrenched Anglo-American cultural antipathy toward wild mushrooms called "mycophobia" by the husband-wife team of Valentina Pavlovna Wasson and R. Gordon Wasson (1957), and "fungophobia" by British naturalist William Delisle Hay (1887:6), who commented,

> [All mushrooms]... are lumped together in one sweeping condemnation. They are looked upon as vegetable vermin, only made to be destroyed. No English eye can see their beauties, their office is unknown, their varieties not regarded.

While mycophobia undoubtedly limits the range of mushroom species labeled edible, a more specific Anglo-American antipathy toward boiled mushrooms has probably also had an effect on English-language authors' determinations of several species' fitness for the table, including *A. muscaria*. In Anglo-American cuisine, boiling mushrooms is an alien concept that approaches taboo status. We boil green vegetables, tubers, and eggs, not mushrooms. The last reference to boiling mushrooms that we could find in a major English-language cookbook was in Robert May's *The Accomplsht Cook* (1660). English 18th-century mushroom cookery practice was to stew, grill, bake, and fry mushrooms, but without parboiling (Glasse 1747; Briggs 1792). This is the practice that entered the American cookbook literature in the 19th century, and is the tradition that North Americans follow to this day (Randolph 1836; Lincoln 1884; Rorer 1902; Rombauer *et al*. 2006). An exception is Kuo (2007), an American field guide author, who is not averse to boiling the mushroom, *Lactarius deceptivus* Peck, *three* times with water changes (a northern European treatment), but nonetheless dismisses *A. muscaria* as "seriously poisonous." On the other hand, most modern field guides in other languages, even those from countries with little or no aversion to boiling mushrooms, clearly label *A. muscaria* as poisonous, with no mention of it being edible if parboiled or of its use as food by some people. Our survey of field guides in other languages, though cursory, included several from mycophilic countries such as Russia, Italy, and Japan (Hongo and Izawa 1994; Testi 1995; Papetti *et al*. 1999; Tat'jana 2007).

It is also significant that some mushrooms - e.g., morels (*Morchella* spp.) and honey mushrooms (*Armillaria* spp.) - are invariably labeled "edible" in English-language field guides despite being toxic raw (Benjamin 1995:278, 358). In other words, there is no consistent logical standard by which a mushroom is judged to be edible or poisonous. Instead, the initial reputation that a mushroom - or any potential food - acquires, for whatever reason, tends to hold sway through weight of precedence. Cultural assessments of a food's safety and desirability can certainly change (see Yamin-Pasternak 2008, this issue), but not easily. Thus peanuts (*Arachis hypogaea* L.) and other tree nuts are in no immediate danger of being labeled poisonous despite causing more than 100 deaths a year in the United States alone (Sampson 2002), while field guide authors list *A. muscaria* as poisonous despite its edibility being solidly established in the 19th century. Furthermore, a particularly litigious culture (such as that of contemporary America) may function as an additional brake on the dissemination of unpopular but scientifically accurate information. The net result, evident in the mushroom edibility literature, is a climate of fear-based ignorance rather than knowledge-based caution. As Douglass (1917b:207) so pungently put it, "With bigoted abstinence on the one hand, with gourmandizing and gluttony on the other and perhaps a bad cook in the kitchen even the most innocent and well-meaning mushroom will acquire a bad reputation."

Field Guides: Science or Culture?

Food choices and cuisine lie at the heart of cultural, regional, and national identity, whereas the taxonomy of nature, at least in modern urban societies, does not. This dichotomy may explain why food choices tend to be resistant to change, while scientific taxonomy embraces change as proof of modernity. The accuracy of the taxonomic and nomenclatural information is scrupulously maintained in field guides from decade to decade because modernity confers credibility. If the taxonomy and nomenclature of a field guide are out-of-date, its credibility suffers, and readers may well doubt the knowledge of the author. The edibility determinations are a significant part of almost all mushroom field guides; indeed, without the edibility information their public appeal would be greatly reduced. Yet the edibility determinations are free from the need to be modern or accurate precisely because they are culturally derived and reflect what it means to be an American or English consumer of wild mushrooms, as opposed to a Chinese or Italian one. As but one example, when the field guide by Thomas (1928) was reissued in a new edition (Thomas 2003), the scientific nomenclature was updated, but the edibility information was not.

The disparity between field guides' treatment of mushroom morphology versus edibility can also be seen in the language. For example, *poisonous* is an intimidating word: attached to a potential foodstuff, it tends to discourage consumption. For the past 250 years, the primary meaning of "poison" has been a small amount of something that causes immense harm, even death (Oxford English Dictionary 2008), yet mushroom field guides routinely apply the label "poisonous" to a wide range of species including those that kill, those that merely upset one's stomach, and those that intoxicate. The imprecise language of mushroom edibility determinations (edible, poisonous) contrasts sharply with the highly precise terminology applied to the morphological features of mushrooms; for example, the surface ornamentation of a mushroom's stalk can be described as squamulose, scabrous, floccose, punctate, reticulate, or glandular-dotted. The difference in language further suggests that the high quality of analytical thought applied to questions of identification and morphology is not applied in the same measure to a mushroom's edibility, and is instead superseded by personal and cultural bias.

There is nothing inherently wrong with teaching edibility in terms of cultural practices as long as the bias is declared. However, modern field guides tend *not* to explicitly declare their bias as Curtis (1777-1798) did when he said of *Agaricus fimetarius* L., "It is not eaten with us." Instead, field guides tend to declare a mushroom species as "poisonous" or "not edible" as if it were an objective truth (see, for example: Lincoff 1981; Bon 1987; Phillips 1991; Jordan and Wheeler 1995; Bessette *et al*. 1997).

The problem of cultural bias in the evaluation of mushroom edibility was recognized in the 19th century when field guides were still a new genre. The Frenchman, Dr. Pouchet (1839), noted many instances in which the absolutist language of mushroom edibility asserted as fact the inedibility of a mushroom that was either published as edible by a different "expert," or was known to be eaten someplace else:

> According to Bulliard, the *Boletus cyanescens* [*Gyroporus cyanescens* (Bull.) Quél] is poisonous, while Bosc says that it is eaten in Piémont; *Agaricus necator* [*Lactarius necator* (Bull.) Pers], considered as a violent poison by many authors, was eaten by M. Letellier without the least problem, and Buxbaum says that the Russians make a great use of it. L'Agaricus acris [*Lactarius piperatus* (L.) Pers.], is also described as poisonous by a great number of specialists, and eaten in many places, according to M. Letellier.

Little has changed since 1839, as mushroom field guides continue to disregard ethnographic and scientific evidence of edibility in favor of an intellectually closed system for assessing mushroom edibility based on personal bias, the culinary and cultural practices of the author's home country, and the information presented in preceding field guides.

Furthermore, the field guide's literary form itself deceives. All of the information about each mushroom appears to derive from one set of objective facts led by the scholarly taxonomic binomial for each species. But while the Linnaean taxonomic system is concerned with mushroom morphology and phylogeny, the edibility determination and information are there to advise *cooks*, not taxonomists. Thus, two entirely different classification systems with different goals, each resting upon a different body of knowledge and arrived at using different methods, are deceptively intermingled; the taxonomic and descriptive information predominates (typically by a ratio of more than 5:1), and the edibility information derives much of its *gravitas* from being embedded in the former. Sitting under the taxonomic umbrella, the edibility information is shaded, as it were, from the glare of objective scrutiny. In summary, mushroom field guide authors teach the science of taxonomy. They *could* teach the science of edibility, but they don't. They teach a cultural lesson, and always have.

Field Guides and the Future

Field guide bias has been an impediment to sound scholarship, as we have shown for Michelot and Melendez-Howell (2003). It may have discouraged ethnographers from seeking information on the consumption of mushrooms they assumed could not be eaten, and it most certainly has limited the number of mushroom tastes, shapes, and textures available to cooks. Therefore, we support Samuel Thayer's (2006:12) insistence that field guide authors provide citations for every fact of edibility or toxicity not derived from personal experience. In his words,

> When the works of authors who abide by [this principle] come to supplant those of sloppy scholarship, the study of wild food plants will be taken seriously again, and the oldest and most beautiful pastime in history will rise from the ashes.

In the last century there has been a dramatic urbanization of the landscape, widespread destruction of mushroom habitat, and a radical transformation of the relationship between people and forests. Both authors have shared the company of traditional mushroom collectors on all the major continents, and, except in the most isolated villages, these people tend to collect many fewer species than their parents, and their parents collect fewer than the grandparents (see Guissou *et al*. 2008, this issue). As with so many practices related to forests, knowledge is being rapidly lost. But if we methodically hunt for the remnants of mushroom knowledge with the obsessive diligence we search for mushrooms hidden under forest leaves, we may still be able to preserve a broad record of human endeavor regarding wild mushroom edibility and preparation, and the role wild mushrooms have played in people's lives prior to mass urbanization. For this hunt we must use focused conferences, field work, laboratory experiments, and the many tools of the Internet to assemble and disseminate information about mushroom edibility and usage from all over the world.

We believe that concerted research will reveal that the record of mushroom usage is far richer, more intricate, and more varied than the modern literature would suggest. Bringing field guide edibility determinations in line with accurate ethnographic and toxicological scholarship would create a body of work that will both preserve culinary information that is at risk of being lost, and facilitate a new mushroom cookery based on the broadest possible definition of edibility. This might seem a daunting task, but it coincides with a renewed and growing interest in local and wild foods (Ghirardini *et al*. 2007) that challenges the homogenizing influences of globalization (a process occurring even with respect to wild mushrooms, as described by Sitta and Floriani 2008, this issue).

As the scope of orally-transmitted mushroom knowledge diminishes in countries where mushroom collecting has been widespread, field guides will play an increasingly important role in shaping human-mushroom relationships. They will supplant parents and village elders as the most significant and obvious sources for information on mushroom identification, ecology, and edibility; indeed, in some countries they already have. But greater influence entails heightened responsibility and a more pressing need to be accurate. For, as we have shown for *Amanita muscaria*, field guides not only reflect and reinforce cultural consensus, they forge it.

Over twenty five years ago, a tiny perfect grisette seduced me into the world of mushrooms. Barely three inches tall, it glowed pearly gray and grew from the middle of my favorite Bay Area hiking trail. The sight of it drew me to my knees. It was too beautiful to disturb, so I sketched it on a bank deposit slip, the only scrap of paper that I had with me. I carried that paper in my wallet for years and eventually identified it as a grisette, a member of the *Amanita vaginata* group, one of the many edible amanita species found here in California.

The hook was set, and amanitas in the wild continued to intrigue me. I obsessively read mushroom field guides, paying particular attention to the amanitas. A desire to eat what I had tentatively identified as a "Coccora" (*Amanita calyptroderma*), a locally popular edible amanita, coupled with a strong sense of self-preservation, caused me to join a local mycological society and begin my mushroom studies in earnest.

Since then, I have become a proponent of the safe and mindful collection and consumption of various edible California amanita species, as well as a mushroom poison identifier and mushroom educator, and I continue to have an abiding passion for all of the members of the genus *Amanita*. It was therefore with great interest that I first learned of the paper discussing *Amanita muscaria* and its use as food by William Rubel and David Arora, in the October 2008 special mushroom issue of the journal *Economic Botany*.

For as long as I have known him, David Arora has recounted the story of the modern day treatment of *muscaria* as an edible species in the Nagano Prefecture of Japan. Along with many others who attended his lectures and forays, I was fascinated by the concept. I was also aware of the many instances of serious *muscaria* poisonings that have occurred both through the ages and in modern times, so I was curious how their argument in the *Economic Botany* paper would proceed.

The title of the article was "A Study of Cultural Bias in Field Guide Determinations of Mushroom Edibility Using the Iconic Mushroom, *Amanita muscaria*, as an Example." The authors start by noting that there is a broad scientific acceptance that *muscaria* toxins are water soluble, and that there are a few isolated practices of people around the world detoxifying and eating *Amanita muscaria*. From this they conclude that somehow "cultural bias" causes North American field guide authors to continue to list *muscaria* as a poisonous rather than edible species (Rubel, Arora, 2008).

But is this really a case of "cultural bias," or is it just good, common sense?

The basic hypothesis of field guide authors' mushroom edibility bias is sound. Any mushroom book that deals with edibility preferences is subject to the whims of its author: their culinary experience, personal judgment, and prevailing opinions all help to determine poisonous and edible designations. Since no one wants to recommend a mushroom that might be harmful to others, it is in everyone's best interest for field guide authors to err on the side of caution, even if you might be aware of exceptions to the rule.

As I read Rubel's arguments and selected quotes in his *muscaria* paper, my uneasiness grew. His several attempts to redefine the word "poisonous" so that it didn't apply to *muscaria* were disturbing. His suggestion that future mushroom book authors should list *muscaria* as an edible species, and that it would be perfectly unremarkable to do so, was also troubling. Do we really want to encourage folks to use less caution about known poisonous species, even if, as mycophagists of long standing, we may know of ways to circumvent these poisons? And finally, I wasn't buying the premise that *muscaria* was commonly accepted as a perfectly safe edible species anywhere in the world.

Amanita muscaria is one of the most beautiful and eye-catching mushrooms found any where. Although *muscaria* is a seriously toxic mushroom, its most abundant toxins - ibotenic acid and its decarboxylation by-product muscimol - are water soluble, and can be leached from the mushroom flesh through careful and prolonged boiling.

Let us note in passing that this method of preparation of course does not work for the deadly, amatoxincontaining, world-spanning amanitas collectively called "Death Caps" and "Destroying Angels." The highly stable and supremely toxic amatoxin molecule is impervious to heat, cold, or acid bath. Amatoxins cannot be removed from mushroom flesh through par-boiling or any other sort of heat or cooking process. Certainly, no one would want to have novice amanita mycophagists generalizing the *muscaria* parboiling detoxification process to these sorts of unequivocally deadly, albeit also delicious tasting, amanita species.

As for *muscaria*, it is true that very small numbers of people around the world have indeed discovered that it can be made edible through careful and sometimes elaborate preparation; but it is also imperative to remember to throw out the water into which the toxins were leached. One American couple who forgot to do so became seriously intoxicated, to the point of damaging both themselves and their household (Beug, 2010)!

Field Guide Bias Si! *Muscaria* as a Safe Edible Species No!

On these basic points (water soluble toxins in *muscaria*, field guide bias) I think that we can all agree. But rather than going on to demonstrate how most field guide authors show bias in all of their edibles' designations, the Rubel/Arora paper chose to present an elaborate justification for the treatment of *muscaria* as a perfectly safe edible species. The authors based this hypothesis upon the evidence that they selected, but I will show that this evidence is incomplete and therefore insufficient for declaring *muscaria* to be a perfectly safe edible species.

As an intellectual exercise, digging through dusty tomes to find a few scattered references to folks who ate *muscaria* as food in the course of history can make interesting reading. Conjecture can be strengthened by selective examples to support a hypothesis. However, it is difficult to prove a hypothesis beyond the shadow of doubt through the fog of centuries. What becomes troubling is when this conjecture and conflation of anecdotal evidence gets stamped with the imprimatur of someone of David Arora's stature, a man to whom many look for answers to mycological questions, especially in terms of mushroom edibility.

The authors' central hypothesis of the purported safe edibility of *Amanita muscaria* soon left the relative obscurity of subscribers to *Economic Botany*, and traveled to the boundless territory of the Internet, with links to the paper on both Rubel's and Arora's websites, in addition to many other places online, such as Wikipedia, Springerlink.com, Ingentaconnect.com, Discoverlife. org, Tititudorancea.org, etc.. Now the paper, with what I believe to be major misconceptions, was being referenced by a wide variety of mushroom enthusiasts worldwide as "common knowledge," and a recipe for the "safe" preparation of *muscaria* was freely shared.

"Edible" *Amanita muscaria*: A Recipe for Disaster?

As public educators, on a topic that is mostly unknown here in North America, I believe that we must consider the impact of our words. Although many experienced mushroomers are aware of the fact that it is possible to remove the toxins from *Amanita muscaria*, it is naïve at best to assume that people will always carefully follow a recipe, especially one that includes a potentially dangerous mushroom. Ironically enough, even the original *muscaria* detoxification recipe that Rubel and Arora provided in the *Economic Botany* article had important numerical conversion errors, listing 250 gm. of *muscaria* as the equivalent of 4 ounces. In the online version of this paper, linked to from his website, Arora changed the amount of *muscaria* in the recipe to the correct weight of 110 gm. (Arora, 2009).

Yet even a perfectly reasonable recipe can have unreasonable translation into a real-time meal. If many folks have difficulties following any recipe, why start with a troublesome and sometimes even dangerous ingredient? I know of at least four folks who had unpleasant experiences after attempting to detoxify *muscaria* at home. One told me of her experiences directly, another wrote it up in great and glorious detail online (Konecney, 2009), and two others published their story in *Mushroom, the Journal of Wild Mushrooming* (Millman, Haff, 2004). Even the recent book *Mycophilia* by Eugenia Bone describes a less than ideal experience (waking up in a chair not remembering anything) after eating *muscaria* as an "edible" species, with two well known Western amateur mycologists who brought the *muscaria* to her vacation home in Colorado (Bone, 2011). Do you think they got the recipe wrong, too, or perhaps didn't care if it ended with the diners in a *muscaria* dream state?

What seems to be a fairly obvious factor that the authors failed to consider was this: the vast majority of folks who would even want to try *muscaria* as an edible are undoubtedly already primed for eating *muscaria* as an entheogen (in layperson's terms: to get high). In other words, they would have even less reason to want to follow exactly the elaborate procedures necessary to make this mushroom wholly non-toxic. For these "psychonauts," a nice, neurotoxic poisoning could be looked upon as a bonus. Pity those poor folks who just want a nice mushroom meal for their families, though, and not a trip to the emergency room. Wouldn't a bit of warning be in order for them?

Redefining Poisonous to Exempt *Muscaria*

According to Rubel , one shouldn't even consider *muscaria* to be poisonous, at least in the strict sense. After all, a small piece won't kill you (Rubel, Arora, 2008). But in fact, although seldom fatal (its deadly designation in many older field guides does indeed seem like "overkill" to most) *muscaria* can certainly be dangerously toxic.

I botenic acid-containing mushrooms (*Amanita pantherina* and *A. muscaria* and their close relatives) are a major cause of serious mushroom poisonings, especially in the Pacific Northwest, often resulting in hospitalizations (Benjamin, 1995; Beug, 2006; Spoerke *et al*, 1994). Usually, these poisonings are self-limiting. The folks who were poisoned, regardless of the reason the mushroom was eaten, have no wish to repeat the experience.

Recent North American Deaths Linked to *Amanita Muscaria* Ingestions

Sometimes the unforeseen results of eating *muscaria* are more serious than "merely" an unpleasant poisoning and hospital stay. The National Poison Data System for 2004, established by the American Association of Poison Control Centers (AAPCC), listed a fatal outcome for a young man who ate 6-10 freeze-dried *muscaria* caps (Watson, 2004). He was discovered in cardiac arrest, and died 10 days later from anoxic brain injury. Another fatal *muscaria* poisoning case from 2007, recounted in a NAMA Toxicology Committee Report in the 2009 issue of *McIlvainea*, tells of an otherwise healthy young man who died twelve hours after ingesting 6 or 7 *muscaria* caps. After falling into a *muscaria*-induced swoon the night before, he was found dead in bed the next morning. The medical examiner who autopsied the corpse labeled it death by mushroom poisoning, since he could find no other contributing cause of death (Beug, 2009), although since there were other drugs involved, the exact cause of death remained unclear (Beug, 2012).

Blithe assurances of the safe and unremarkable edibility of *muscaria* would be cold comfort indeed to the families of the two separate cases of young men who ate *muscaria* and then fell into comas. While in this helpless state, one froze to death while camping, and the other died after aspirating vomitus (Beug, 2006).

In a more recent case, recounted to me by Marilyn Shaw, toxicology expert and poison identifier for the Rocky Mountain Poison Control, a young man in Aurora, Colorado narrowly escaped death when he was discovered naked and unconscious, with a severely lowered body temperature and in cardiac arrest, after the recreational ingestion of *muscaria* (Shaw, 2012).

Who knows how many other incidental deaths after *muscaria* ingestion there may have been? Testing for muscimol levels is hardly part of a coroner's normal toxicology panel (Benjamin, 2012).

Recent *Muscaria* Deaths in the Southern Hemisphere

Documented deaths from the ingestion of *Amanita muscaria* are not restricted to North America. Formerly found only in the Northern hemisphere, *Amanita muscaria* has been inadvertently introduced to the Southern hemisphere in *Pinus* tree farms, producing a novel, toxic species of red amanita in places where no ibotenic acid-containing amanitas have been found before. This has had tragic consequences in Tanzania, where locals had safely gathered a number of choice, edible amanita species for many generations, without a thought to careful identifications. Often only the amanita caps were gathered, leaving the bases buried. A *muscaria* cap in age, with its warts removed and with a striate margin, can closely resemble local edible species in Amanita section Caesarea.

While Finnish mycologists were in Tanzania describing some of these local, edible amanita species for science, they consulted on a *muscaria* poisoning case, where two women and a child were poisoned and in hospital. After reassuring doctors that the poisonings would resolve on their own, since that was indeed their experience with *muscaria* poisonings in Scandinavia, they were horrified to learn that one of the women died from her meal the next day. Upon further interviews with other Tanzanian locals gathering amanitas, they discovered even more recent *muscaria* deaths (Harkonen, 1994).

Our Most Famous North American *Muscaria* Fatality

If one is willing to go back a little over a hundred years ago, you discover the unfortunate death of Italian diplomat Count de Vecchj, who requested amanita mushrooms from the Virginia countryside for his breakfast, believing them to be local examples of *Amanita caesarea*. Unfortunately, the mushrooms that were brought to and consumed by the Count were not the choice, edible *caesarea* of Italy, but the toxic *muscaria*, and the Count ate a gluttonous meal of somewhere between a dozen and two dozen caps, which resulted in convulsions so great that he broke his hotel bed (Rose, 2006).

The Count, who prided himself upon his mushroom identification skills, died from his meal. Out of his death and its ensuing lurid and widespread publicity, sprang a renewed North American interest in mushroom societies, especially in the Northeast, to provide much needed public education about edible and poisonous wild mushrooms (Rose, 2006).

On the face of all of this evidence to the contrary, it is disingenuous at best to consider *muscaria* to not be a poisonous mushroom. But poisonous is an off-putting word, pleads Rubel, a fan of *muscaria* eating to be sure.

Evidence for *Amanita muscaria* as a Poisonous Mushroom

In his *muscaria* paper, Rubel states: "Listing *A. muscaria* as edible rather than poisonous is a completely unremarkable judgment in a culinary context." Here is how Rubel describes the effects of *muscaria* ingestion on his website:

> "*Amanita muscaria* is not poisonous in the sense that it can kill you. It is poisonous in the sense that if not parboiled in plentiful water (the "toxins" are water soluble), then raw or undercooked mushrooms eaten (in moderation) will cause you to become inebriated and possible nauseous" (Rubel, 2011).

The above statement assumes that future *muscaria* eaters, perhaps lulled into complacency by assurances that *muscaria* isn't *really* poisonous, will use moderation and carefully follow a recipe. But wouldn't a stronger emphasis on its very real toxicity be a better way to get any future *muscaria* mycophagists to be cautious in its preparation and consumption? Or maybe reject the idea of eating *muscaria* as an edible species altogether?

Here's what the *Emergency Physicians Monthly* website had to say about *Amanita muscaria* and the many ibotenic acid poisonings that they have collectively observed:

> A toxic dose in adults is approximately 6 mg. muscimol or 60 mg. ibotenic acid - the amount found in one cap of *Amanita muscaria*. However, the amount and ratio of chemical compounds per mushroom varies widely from region to region and season to season. Spring and summer mushrooms have been reported to contain up to 10 times as much ibotenic acid and muscimol compared to autumn specimens. Toxic components are not distributed uniformly in the mushroom. Most of the muscimol and ibotenic are contained in the cap or pileus. A fatal dose has been calculated at approximately 15 caps.

Fly agarics are known for unpredictable clinical effects which can be highly variable between individuals exposed to similar doses. Symptoms typically appear after 30 to 90 minutes and peak within three hours. Certain effects can last for days, but the majority of cases completely recover within 12 to 24 hours. Unlike other toxic mushroom ingestions, vomiting is uncommon. Patients may exhibit ataxia, auditory and visual hallucinations (described as sliding vision and "the ability to see through walls"), as well as hysteria. Central nervous system depression, coma, myoclonic jerking, hyperkinetic behavior, and seizures have been described in larger doses. Retrograde amnesia and somnolence can result following recovery. (Erickson, 2010)

Whoa, that sounds rather more unpleasant than "inebriation" and "mild nausea," doesn't it?

Let's take the informed opinion of another North American mycologist and toxicologist, Michael Beug, PhD. Beug fields poisoning calls in the Pacific Northwest, where muscimol poisonings account for the majority of all serious mushroom poisonings. He had also heard that some Russians living outside Moscow eat detoxified *muscaria* as an edible species (through the work of R. Gordon Wasson and later from Dr. Daniel Stuntz), but he doesn't know how many do so, nor to what degree this is practiced. Here is what Beug had to say about eating *Amanita muscaria*:

Both *Amanita muscaria* and *Amanita pantherina* are large, showy, and delicious, though poisonous mushrooms (unless cooked by boiling them and then discarding the water, but if you don't get rid of *all* the water, look out!). Though some people in Russia apparently parboil and eat *Amanita muscaria*, it is not a practice I recommend. *Amanita muscaria* and *Amanita pantherina* are frequently eaten intentionally by people seeking to get high and are also frequently eaten by mistake (believe it or not, often from people thinking they had an *Agaricus*). The "trip" from *Amanita muscaria* and *Amanita pantherina* is generally not pleasant and involves hospitals more predominately than hallucinations. (Beug, 2004)

Attitudes about Eating *Amanita muscaria* from Outside of North America

A very different viewpoint of Russian fungal proclivities is provided by Gary Lincoff, mycologist and author of *The Audubon Society Field Guide to North American Mushrooms*. Lincoff and a group of 15 or so others traveled to the Kamchatka Peninsula of Russia in 2004 and 2005. Their purpose was to investigate firsthand the statements made by Gordon Wasson about *Amanita muscaria* use in Siberia, taken from his 1968 book, *Soma: Divine Mushroom of Immortality*. Here is what Lincoff had to say about local attitudes towards *muscaria*:

> The hunter-gatherer peoples differ from the Russians in many ways but none more dramatic than in their use of mushrooms. The Russians hunt many kinds of edible mushrooms but avoid one mushroom in particular, the fly-agaric, *Amanita muscaria*, which they regard as very poisonous. In fact, it is used in Russia and Europe as a fly-killer: the mushroom is placed in a cup of milk to which flies are attracted and become numbed. The hunter-gatherers, on the other hand, collect and eat just one single mushroom, the same fly-agaric that the Russians avoid. (Lincoff, 2005)

The Eastern Siberian Koryak and Even (or Evensk) tribes, the hunter-gatherers to which Lincoff refers, eat their *muscaria* sun-dried and uncooked, for maximum mind-altering potency. It is used as a sort of tonic within that traditional society, especially by the elderly. It is not eaten as a food species, but as medicine.

Russian mycologist Tatiana Bulyankova, a scientist from Western Siberia who has been contributing field observations to the popular website Mushroomobserver.org, sent me a long letter about firsthand Russian mushroom eating practices. She also spoke laughingly about how in Russia, American field guide authors were roundly ignored, and warned me that it was pretty impossible to generalize anything about a country the size of Russia, or as she put it, 1/7 of all land mass. Point taken, Tatiana!

Here is what she had to say about *Amanita muscaria*:

> The Fly Agaric, predictably, is very common here (and everywhere else in cold to temperate-climate Russia, I guess). It is the symbol of all toxic mushrooms here, I'd even say it's the symbol of poison. It's featured in countless books, cartoons, artworks... everyone knows that it's poisonous. Of course there are young idiots who try it as a recreational drug but that's a bad influence of the Internet, I guess. It's also consumed by tribe shamans of Yugra, Yakutia and other Northern territories but it's something I've only read in the books. (Bulyankova, 2011)

I think we may safely draw the conclusion that even in obsessively fungiphilic Russia, the commonsense cultural bias is *against* eating *Amanita muscaria* as an edible.

A quick survey of various field guides and online sources where the eating of *muscaria* as an edible species is mentioned shows very little empirical or even local evidence to bolster the claims - most *muscaria* eating was reported from elsewhere. A modern Lithuanian field guide stated that *muscaria* was poisonous, but also: "eaten in mountainous France and Austria." No word about Lithuanian edibility practices, though, despite an apparent historical tradition of *muscaria* inebriation.

The main market for *muscaria* in Eastern Europe seems to be in high potency, dried *muscaria* caps, harvested in Latvia and Bulgaria, and then sold online for "scientific purposes." Beware of what is sometimes deadly home research.

George Atkinson, in his 1900 mushroom book *Studies in American Fungi*, claimed that *muscaria* was: "eaten as food in parts of France and Russia, and sometimes in North America," but again, this is repeating information drawn from other sources without explicit verification of facts.

Bruno Cetto's more recent Italian mushroom guide, *I Funghi dal Vero*, Vol. 1, claims that *muscaria* was "eaten cooked and pickled in Russia, France and the Lake Garda region" of Italy. Again, there is no verification of these claims; and the information appears to be merely copied from one source to another without citation. There may well be a very few folks in Russia that eat *muscaria* as an edible species, and perhaps Pouchet (detailed later in this essay) managed to convince some of the poor to do so in France as well, but these are hardly widespread practices.

A Food of Desperation in Italy

Attempting to track down some of the Italian *muscaria* eating references from the Lake La Garda region, (prior to WWII), I came up with the following, from Pierluigi Cornacchia's online article, "*L'Amanita muscaria in Italia*". This modern day writer remarks upon the difficulty of tracking down these old references, even within Italy, and lists many local variations of common names for *muscaria*, all of which refer to its poisonous properties. Here are two quoted instances where locals in the past had detoxified and eaten *muscaria* (Cornacchia, 2006):

> F. Cavara (1897) confirmed that in Vallombrosa (Firenze) *Amanita muscaria* was commonly consumed and stated, "I can assure you that many report, in some countries of Tuscany, for example above Pontassieve, in late autumn, this agaric is harvested in quantity and put to soak in basins where water is changed every day, for 10 or 12 days, after that is treated like other edible fungi and found excellent. It helps [in the preservation] that the season is cold."
>
> This information has been verified directly in the field. I have been collecting testimonies of elderly inhabitants of the villages of Reggello, Saltino, Pian di Melosa and Vallombrosa. The ovolo malefic ["evil egg"],[1] as it is called in those parts, was usually consumed after appropriate preparations (boiling with vinegar, salting, rinsing with running water). According to the testimonies, the use of this fungus as food, which lasted until the beginning of World War II, was due solely to the economic problems.
>
> [1] Presumably the good mushroom eggs in that part of the country would be caesarea or the Coccora. - LS

In other words, the *ovolo malefic* was a food of desperation, and the preparation needed to make it edible was hardly trivial.

Pouchet's Place in History

Another country for which the historical and "culturally accepted" practice of eating *muscaria* has been claimed is France. Although I could find zero evidence of current *muscaria* eating practices, and in fact a respected French mycologist of my acquaintance scoffed at the very idea (Wuilbaut, 2012), in his *muscaria* paper Rubel devoted a good bit of ink to the work of a Frenchman and scientist who apparently tried to popularize *muscaria* eating amongst the poor in the 1800s: Félix Archimède Pouchet.

Pouchet in his time - like Rubel in ours - equated the preparation of and eating of poisonous *muscaria* to poisonous manioc, a staple food across Africa. Manioc starts out deadly poisonous and is made edible through careful preparation. But this is a poor analogy. Nobody in modern day North America *needs* to eat *muscaria* to survive. Fresh or dried, dangerously poisonous, cyanide containing manioc is often the only high quality starch available to millions, mostly across Africa, where it can be grown in poor soil and under drought conditions. Its deadly toxins also discourage crop predation. But it can have faulty preparation as well, and can cause some very serious illnesses.

Perhaps, like me, you had never heard of Pouchet? He was indeed a respected scientist of his time, and a popular science writer, but also one of the strongest proponents of the theory of spontaneous generation. Would it be safe to hold the rest of his science up to a modern light?

To prove that *muscaria* was a safe edible species, he fed dogs both *muscaria*-infused broth (to show that *muscaria* toxins were water soluble; the dogs died) and boiled and drained *muscaria* (the dogs survived) (Pouchet, 1839). He also claimed to have "fattened dogs" on boiled *muscaria*, but experimental details for that experiment were not available and fortunately for local dogs, none of these experiments were repeated, to my knowledge, by any other researchers. Pouchet's work was widely cited by others at the time (Rubel, Arora, 2008). But do a few dog studies really translate to human safety?

If *muscaria* was such a wonderful and safe edible species, why would Pouchet limit its use to the poor?

Pouchet is best known today for being a fierce public critic of Louis Pasteur, another scientist of the day who publicly disputed the commonly held theory of spontaneous generation. Pasteur was, of course, the French scientist who managed to keep lots of folks from dying in various horrible ways, by creating the process of pasteurization that prevented formerly widespread milk fevers (typhoid and scarlet fever, septic sore throat, diphtheria, and diarrheal diseases) and for creating life-saving vaccines against the scourges of rabies and anthrax (Swayze and Reed, 1978).

Pasteur gave a public demonstration, to which Pouchet was formally invited, to prove once and for all that it was in fact microorganisms, not spontaneous generation, that created life where there was apparently none before. Pasteur gave birth to the science of microbiology.

Pouchet was a no-show at this triumphant exhibition by Pasteur, but he did give us boiled *muscaria* for the poor as *his* legacy.

Sketchy historical evidence, couched in terms of "it is said" and "it is reported that" of *muscaria* eating around the world should not be used to bolster claims of its safety. There is no evidence that it was ever a commonly accepted edible species anywhere in the world, and for good reason.

Amanita muscaria Consumption in Japan: Exception not the Rule

What about in Japan, specifically the Nagano Prefecture, where the consumption of *muscaria* as an edible species is often cited?

I first learned about the unusual practice of mundane (as opposed to ritual) *muscaria* munching in David Arora's annual Mendocino Thanksgiving Foray, an event that I attended, both as a participant and as staff, for over a dozen years running. The story that he told was both fascinating and charming: he claimed to have passed local mushroom hunters along a Nagano mountainside, whose baskets were filled with *muscaria*. Arora's basket brimmed with *Boletus edulis*, and they both looked at each others' finds in horror! Great theatre, but what is the deeper reality?

While visiting the Nagano Prefecture, Arora tried the *muscaria* pickles that are a traditional but in fact seldom eaten food. Nagano Prefecture is the only Japanese province wholly cut off from the sea. The practice of pickling *muscaria* began after "salt roads" were built from the coast into the mountains over a hundred years ago.

In addition to Arora's experiences there, a young man by the name of Allan Phipps, who spoke and understood the Japanese language, spent a good bit of time researching the localized treatment of *muscaria* as an edible species for his Master's Thesis at Florida International University. His results were quite interesting, and showed that eating *muscaria* is hardly typical for the Japanese culture as a whole (Phipps, 2000).

Phipps' thesis showed that local consumption of *muscaria* as an edible species is severely restricted, in both amounts of *muscaria* eaten as well as in general acceptance of the practice. *Muscaria* eating takes place not in the already limited Nagano Prefecture as a whole, but merely as a subset of people in one town: Sanada Town, with a population around 10,000. Within that subset, Phipps located 123 *muscaria*-favorable individuals, and from them he winnowed out ten most likely subjects for interviews (Phipps, 2000, p. 29).

Even more telling, he discovered these interview subjects by attending local mushroom fairs (three per year in Sanada Town), of a similar style to our North American mushroom fairs, with general collecting on one day, identification by local experts on the next, and then public displays with labeled mushrooms. At all of these fairs, within ground zero of *muscaria* eating in Japan, displays of *muscaria* were clearly labeled as poisonous mushrooms! These fairs were sponsored by the Japanese government and local insurance companies in hopes of preventing *mushroom poisonings* (my emphasis). Phipps found his interview subjects by hanging out at the *muscaria* display table and targeting those that scoffed at the poison label (Phipps, 2000, p. 29).

Indeed, within Sanada Town only (adjoining towns within the Nagano Prefecture treat *muscaria* as a wholly poisonous mushroom) *muscaria* is made into pickles, which have been shown through careful lab analysis to contain zero amounts of toxins. These pickles are then eaten in small amounts, for special occasions such as the New Year.

The process of making them is extremely involved (Phipps, 2000, p. 62). There are four steps to pickling *muscaria*, as relayed to Phipps by Sanada Town *muscaria* pickle devotees: boiling for ten minutes, or five minutes three times, washing, salting and soaking. Mushrooms are often initially boiled until all color is removed; the water is always tossed. After boiling, the mushrooms are rinsed under running water for 1-3 minutes. Mushrooms are then packed in salt and compressed, and left for at least one month. Prior to consumption, pickles were soaked for several hours or overnight to remove the salt (and any remaining traces of the toxins). These *muscaria* pickles were then used as culinary accents, not meals. They were and still are eaten for special occasions only, or served to special guests (Phipps. 2000, p. 37).

But frankly, the above method to prepare a wholly non-toxic snack does not sound like a reasonable recipe for today's modern-day, want-it-now cooks. In fact, the tradition is dying in Sanada Town, because modern Japanese youth can't be bothered to go through all the preparation steps to make a toxic mushroom edible (Phipps, 2000).

Phipps' thesis that unboiled *muscaria* is also grilled and eaten in *small* quantities (Phipps' emphasis) by certain local men. Here is what a subject told Phipps:

> "He compared the experience of eating a known poisonous mushroom like *muscaria* to eating fugu, the poisonous blowfish. The combined thrill of eating something poisonous and the outstanding taste makes this mushroom worth the risk."

But only small amounts are ever eaten, and there remains a good bit of paranoia attached to the process, with the men fearful of possible accumulative effects in addition to directly toxic ones. In other words, despite the limited local tradition of eating *muscaria* as an edible species, they are still uneasy about actually eating it (Phipps, 2000, pg. 41).

It is safe to say that *muscaria* eating in Japan is by no means a culturally accepted practice - and as even Rubel pointed out, in apparent disbelief, even Japanese field guides list *muscaria* as an unambiguously toxic mushroom.

Limited Historical Evidence of *muscaria* Consumption in North America

Rubel and Arora were "intrigued" by unsubstantiated reports of African-Americans in the southern states in the 1800s that may have eaten *muscaria*, but convincing evidence is lacking. Even if it were true, what reasons might an enslaved people have for eating *muscaria*? Was it another food of desperation? Or perhaps it was even eaten unboiled for its entheogenic strengthening effects, qualities a desperate slave could surely use. This is of course mere conjecture on my part, but so is any other imagined historical scenario.

A single verified example of historical *muscaria* eating in the Washington, D.C. area was also cited by Rubel, in hopes, I believe, of showing that it was at one time an accepted practice here in North America, so why not now? But even here in North America the evidence is not only flimsy but rather conjectural. Yes, there was apparently one black woman mushroom vendor who prepared *muscaria* for her table, discovered at a mushroom market outside of Washington, D.C. in the late 1800s, and of course that famous fatal encounter with *muscaria* by the late Count de Vecchj.

Even more telling to me than one individual with out-of-thenorm eating habits was this quote by Frederick Vernon Coville - a botanist who in 1898 investigated the recent, sensational *muscaria* poisoning of Count de Vecchj for the U.S. Department of Agriculture. Coville searched for potential sources of *muscaria* at the Washington, D.C., K Street Market:

> Though *most* [my emphasis] of the colored women of the markets look upon the species [*Amanita muscaria*] with horror *one* [my emphasis] of them recited in detail how she was in the habit of

> cooking it. (Coville, 1898)

Oddly, in his *muscaria* paper Rubel also showed the entire quote, but somehow didn't derive the same meaning that I did: that eating *muscaria* was *not* a common practice, but one observed by a single individual among many others who rightly feared it. Rubel went on to seemingly conjecture that because this one woman's recipe (again, an anomaly among the rest of the mushroom sellers) for *muscaria* was printed in a USDA publication (Coville, 1898), and then cited by others, it was therefore a locally acceptable practice.

I drew a very different conclusion from these same facts: that the behavior of one woman does not a trend make, and that in fact, the publication of these recipes and the quotes about the market seller were widely cited and published for the very same reason that this topic gets press today: its shock value.

The *muscaria* prep by the African American market woman was quite elaborate, and the mushroom hardly resembled a *muscaria* when it was done: the cap was peeled, the stipe was peeled and the gills were removed. The remaining mushroom bits were then parboiled and the boiling water tossed before cooking. Coville went on to suggest that since, as was believed at the time, most of the toxins were contained in the gills and the cap cuticle, parboiling would have most certainly removed any remaining toxins, and he praised her ability to be able to detoxify a known poisonous mushroom without a scientific background. But he was hardly advocating its use.

It is possible that some misconstrued Coville's remarks as a recommendation that *muscaria* be treated as an edible species. A few months later, in a revised version of the original USDA Circular 13, Coville firmly recommended that no one eat this mushroom, as did physicians during the same time period who were writing for the medical rather than the botanical community. Here is his quote:

> this process (of *muscaria* preparation) is cited not to recommend its wider use, but as a matter of general interest. The writer's recommendation is that a mushroom containing such a deadly poison should not be used for food in any form. (Coville, 1898, revised)

Coville also noted in the revision of USDA Circular 13 that the *muscaria* that poisoned the Count was not purchased at the K Street Market, but rather was brought to him from the Virginia countryside by a countryman who delivered it "under protest" to the Count.

As an added public safety precaution, *muscaria* selling was banned at local, Washington, D.C. markets, shortly after Coville's original article appeared (Chestnut, V.K, 1898). But there is no evidence that it was ever for sale in these markets to begin with.

Lacking in many of these historical, eating-*muscaria*-as-an-edible accounts are first hand reports of the effects, or lack thereof, post-ingestion, but there is certainly a broadly based fear of eating *muscaria*, here and across the world. This is reflected in the universal treatment of *muscaria* as a poisonous mushroom by mushroom field guides worldwide, including those countries with a strong mycophilic and mycophagic history, like Europe (Courtecuisse, 1994) and Japan (Hongo, Izawa, 1994).

Amanita muscaria Fed to Participants in Arora Forays

What about modern day use of *muscaria* here in North America? In his paper, Rubel states that David Arora has served *muscaria* to hundreds as a justification for its safety as an edible, and those numbers are probably true. But I would lay wager, based on my first hand evidence, that none of them ate a full meal of it; and the kitchen preparation for their *muscaria* tastings included thin slicing, several boilings, carefully measured waters (thrown out between batches) and a good splash of vinegar at the end. That last seems more for good measure than for any real benefit.

I was at the first Mendocino California foray, back in the 90s, when Arora served about 70 of us boiled *muscaria*, and I participated in about a dozen forays after that one. Most folks, with a bit of peer pressure and the reassurances of the "god of mushrooms" would try a piece or two - though, according to one of the people who passed the mushrooms around, at least a third of the group declined. Several folks that I have talked to who attended those forays did not wish to repeat the experience of eating parboiled *muscaria*, and who knows how many others, over the years, felt the same way? Like the Japanese gentlemen in Nagano Prefecture, they were thrilled by their daring, but still uneasy about eating a mushroom widely believed to be poisonous.

Peer Reviewed is not the Same as Peer Approved

In correspondence with me, Rubel apparently attempted to bolster his claims about the safety of *muscaria* as an edible species by informing me that he and Arora had published their paper in a peer-reviewed journal (Rubel, 2009). But since only two of his reviewers were actual toxicologists (Michael Beug, PhD and Denis Benjamin, MD) and they both had issues with the paper as originally presented to them (neither read the final version), I was hardly reassured (Beug, 2009; Benjamin, 2009). Dr. Benjamin informed me that his opinions upon this topic were undergoing some evolution and he asked to not be quoted here, but Dr. Beug had no such qualms. Here is what he told me, and I quote:

> "I did not review the final version of the [*muscaria*] paper but was highly critical of the draft and recommended that it not be published" (Beug, 2012).

Does it count as much if the peers who review your work and are intimately familiar with toxic mushrooms pan it?

Evaluate All of the Evidence and Decide for Yourselves

I will not go through a point by point rebuttal of the Rubel/Arora paper, although I have certainly been doing so in my mind and in various forums online, ever since I first read it over five years ago. I would hope by now that you the reader are starting to see the bigger picture on your own: that despite the fact that a few people, here and there around the world, have indeed eaten *Amanita muscaria* after elaborate detoxification preparations, it is hardly a broadly accepted practice to eat *muscaria* as an edible species anywhere, nor has it ever been so. And it is preposterous to pretend that it is sometimes not a dangerously poisonous mushroom, when there is a wealth of evidence to the contrary.

When field guides both here and abroad list *Amanita muscaria* as a toxic mushroom they are representing both the universal cultural and common sense norm. Perhaps these various American field guide authors, scoffed at by Rubel, who list *muscaria* as a poisonous mushroom, were more concerned with the safety of innocent foragers rather than presenting all of the possible ways that one might circumvent the poisons?

As new mycophagists delve deeper into the study of mushrooms in their readings of other places and times, perhaps they will be tempted to try a piece or two of *muscaria*, boiled or unboiled. But to recommend its safe practice as an edible species, with the justification that it was ever commonly eaten in other places and has little toxic downside, is a highly implausible parsing of history.

In edible *Amanita* lectures that I have given around the country, I often cite the official United Nations Food and Agricultural Organization (FAO) document on edible fungi, where dozens of species of edible amanitas, among many, many other species of edible mushrooms, are listed by name. These are all amanitas, from *caesarea* to *zambiana*, commonly eaten or sold in markets around the world. This list even includes some *Amanita* species that might reasonably give us the willies, like *Amanita manginiana*, an edible, market amanita from China that is related to and even resembles *Amanita phalloides* (Boa, 2004). But even in this very even-handed, strongly fungiphilic international document, *muscaria* is listed not as an edible but as a medicinal mushroom. Even more emphatically, the U.N. actually proposed a *resolution* against its sale and use as an edible species:

> Article 622 - None of the genera of poisonous mushrooms listed hereinafter may be used as food, *even if they have undergone special treatments to deprive them of their toxic principles* [italics mine]:
>
> *Amanita*: Mushrooms with fleshy caps colored green (Green *Amanita* or *Amanita phalloides*), or red with white warts (Fly Agaric or *Amanita muscaria*)...

Has it started to sink in yet? That maybe, just maybe, more than a little caution is called for when considering

Amanita muscaria as an edible species?

In the interest of full disclosure, I admit that I have personally eaten very small amounts of *Amanita muscaria* as an edible three times: once, at a long-ago Arora foray, where it was first par-boiled (slimy, tasteless, but still thrilling in a naughty way), once at a camping foray at Salt Point State Park, on the California Coast, where it was grilled by a master Japanese chef (delicious; the best amanita that I ever ate), and once atop pizza, after rehydrating dried *muscaria* mushrooms and throwing out the pretty red water. And yet, I believe that to encourage folks to eat *muscaria* is a bad idea, and I feel safe in saying that the vast majority of the rational, mushroom-loving world agrees with me.

Ironically, perhaps Den is Benjamin's recent satirical piece on *muscaria* eating in FUNGI magazine (Winter, 2011), really does hold the answer: if you must recommend the eating of *muscaria*, treat it as a poisonous mushroom that can be presented as a daring culinary adventure - the land-based American fugu experience, if you will. Go ahead, flirt with danger and have a *muscaria* snack at some future foray or in the privacy of your own home; certainly a piece or two of *muscaria* with the crap boiled out of it won't kill you, and then you'll have those bragging rights (Benjamin, 2011).

But please, gentlemen, don't tout *Amanita muscaria* as a perfectly reasonable edible species with a long history of safe usage and cultural acceptance both here and overseas, when the evidence clearly refutes your claim. And if you do someday revise *Mushrooms Demystified*, Mr. Arora, please, err on the side of caution. The many people who look to you for personal safety as well as honest answers will appreciate it.

Muscaria Treatment in American Mushroom Field Guides

Just to see what all the fuss was about in the treatment of *muscaria* by American mushroom field guide authors, I read the *muscaria* edibility descriptions in over a dozen modern guides that I own. All authors, reasonably enough, cited *muscaria* as a toxic mushroom. None, other than McIlvaine's *One Thousand American Fungi*, cited it as deadly. Some mentioned its potential hallucinogenic properties. Some talked about its historic use as an inebriant. The most recent mushroom field guide from California, *A Field Guide to Mushrooms of Western North America* (Davis *et al*, 2012), touched upon some of this recent edibility controversy by expanding a bit upon the usual dismissive toxicity statements. They stated that *muscaria* was:

> Poisonous and hallucinogenic; the toxins are water soluble, but given the preparation required to remove the toxins, this is not a good mushroom for the table.

The strongest argument against its use, however, was this one, from a mushroom field guide published in 1986:

> Poisonous and hallucinogenic. Fatalities are extremely rare, but it is undoubtedly dangerous in large or even moderate doses. Too many people have had unpleasant experiences for me to recommend it.

The author? David Arora, in *Mushrooms Demystified* (Arora, 1986).

Those wise words still ring true today.

Summary

In reconstructing early uses of psychotogens in Mesoamerica, mushrooms have occupied the attention of botanists and anthropologists almost to the exclusion of other plant motifs. Not all of the images and literary fragments extant lend themselves to mycological interpretation. Some authors have interpreted the peltate leaves and flower buds of the psychotogen *Nymphaea ampla* as being green mushrooms and/or stalked sea shells. The context of presentation, information on the water lily in Maya antiquity, and recent information on the chemistry of this white water lily suggest that we must reassess the role of *Nymphaea ampla*. In a reevaluation of these ancient literary and iconographic sources, it would seem that both mushrooms and water lilies emerge as important ritual psychotogens. While the contextual use of mushrooms is well known, the water lily has been largely ignored. This presentation provides some perspective on both of these important New World narcotics.

The antiquity of mushroom use in Mesoamerica is lost to us, but we are able to date mushroom veneration to at least 100 B.C. based upon the discovery of nine miniature mushroom stones in a late pre-Classic to early-Classic sites near Guatemala City. Progressive finds have been made from Vera Cruz in the north to El Salvador and Honduras in the south. The nature of these mushroom stones and the distribution of mushroom cults were documented by Mayer (1977) who gave dimensions of stones and associated figures. He recorded over 290 such effigies.

Several concepts regarding mushroom stones have been advanced. The 19th century idea that these were the products of cults of phallic worship have been discarded. Rose (1977) has suggested that they may have been used to form rubber balls used in the sacred ball games of the ancient Maya. While this idea may have some validity, it does not explain the miniature stones, and those that have associated metates for grinding. Furst (1976) discovered entries in Quiche and Cakchiquel dictionaries dating from *circa* 1550 and 1690 B.C., respectively. These indicate an association between the mushroom and the underworld, and the mushroom and the loss of one's judgement. Mayer (1977) indicates that the dictionary of Fray Thomas Coto of *circa* 1690 makes specific mention of mushrooms that inebriate. Ethnomycologists no longer doubt the importance of the mushrooms that inebriate to the functions of priestly castes in ancient Mesoamerica. The tradition as it has evolved to the present day has been documented by Wasson (1974) in a word by word transcription of the *Velada* of María Sabina as well as through musical documentation.

Initial field data on hallucinogenic fungi came from Weitlaner's accounts of his witnessing holy rites involving sacred mushrooms, *teonanactl*, and the studies in 1938 and 1939 by Schultes (1940) in the area of Oaxaca. It was the collections of Schultes that provided positive identification of several species of *Psilocybe* and *Paneolus* that were hallucinogenic. These early studies spurred R. Gordon Wasson on to work with his wife and colleague Valentina on the context of mushroom use in this area among the Mazatecs and others. Collaboration between the French mycologist Roger Heim and Wasson (1958) provided a volume of great importance in advancing ideas in the area of ethnomycology. The primary corpus of their work was extended by Heim *et al*. in 1967. Since both of these volumes appeared in French, much of the information of these investigators was relegated to small bodies of scholars. With the publication in 1980 of Wasson's book, *The Wondrous Mushroom*, we have a fine synopsis of the mushrooms that are used in a ritual context in Mexico and Mesoamerica.

The field of ethnomycology has been greatly enhanced by Wasson's recent publication. Despite the erudition of Wasson's meticulous scholarship, there are elements in this book that disturb the ethnobotanist. These are the same elements that appeared in the earlier collaborations with Heim. Specifically, the assertion that the motifs associated with water are green basidiomycetes. Further, the interpretation of Nahuatl verses in a mycological context seems inappropriate. It is the purpose of this paper to indicate that these motifs and verses are better suited to the white water lily, *Nymphaea ampla*, and that this plant has psychotropic qualities that would suit the ritual nature of the iconography and poetic depictions.

In recent years we have seen the appearance of several papers suggesting that certain water lilies (*Nymphaea*) have served as hallucinogens in Maya civilizations and are still in use in some areas of Chiapas (Dobkin de Rios, 1974; Diaz, 1977; Emboden, 1979b and 1981). The concept that water lilies might be used as ritual psychotogens was extended to ancient Egyptian civilizations (Emboden, 1979a).

The collective evidence on water lilies in the old world and the new world suggest a contextual use as a ritual psychotogen. This evidence has been distilled from Maya and post-Maya ceramics, codices, stone reliefs and frescos. The ancient Egyptians left similar information in tomb sculpture, ceramics, frescos and papyri (Emboden, 1979a).

It is the assertion of Wasson (1980) that many of the pictorial images found in an aquatic context in ancient cultures of Mexico are mushrooms that induce hallucinations, or in Wasson's usage (*fide* Ruck) these are entheogens. The aqueous environments in which these are found bespeak the sacred nature of water and purification. The color green that these alleged basidiomycetes exhibit is indicative of holiness.

I would propose an alternative hypothesis. In so doing, my reasoning must be based upon interpretation rather than sound scientific evidence. I would not wish to detract from the presentation of Wasson, but botanical reasoning and familiarity with the imagery presented compels me to suggest a more plausible explanation of green, aqueous basidiomycetes. I shall review some of the same texts, images, and verses that have been dealt with by Wasson, and I shall add evidence from additional sources.

I cannot subscribe to the notion that those who take exception to a mycological interpretation of green, aquatic mushrooms are all "mycophobes". We are all searching for the most accurate and consistent presensation of data that are derived from sources that are often oblique, elliptical and highly stylized. This study should be regarded as a search for clarity and understanding, and not a challenge to the fine scholarship of R. Gordon Wasson, a man for whom I have great admiration.

In dealing with flowers in Nahuatl poetry, the subject of chapter 4 in Wasson (1980), Father Garibay's *Poesia Nahuatl* (1968) is cited with considerable frequency. In the Garibay translations there is frequent mention of flowers in the context of inebriation. Although Garibay denies any hallucinogenic (entheogenic) elements as being apparent in these texts, we must support Wasson in his stance that the poetry is flat and stale without "bone and sinew, the blood and muscle of their (Nahua nobles) poetry". What, may be argued, is the genus and species of "flores" referred to in these texts. Perhaps we go too far if we accept Wasson's assertion that "flores is the trope for the entheogens". This would seem to force much of the poetry into a sort of procrustean bed. In some instances it would seem that the flowers are possessed of beauty and fragance and little more; however, in other verses the poet is explicit in speaking of their inebriating qualities. For example, "*De dónde las flores que embrigan?*" (I, p. 77). "From whence come the flowers that inebriate?" This is addressed to the sacerdotes or priests, those who would be the keepers of such mysteries. Likewise, "*He llegado a su presencia y hago estremecer… mis flores embriagadores*." (II, pp. 34-35). "Having arrived in your presence, I wave my inebriating flowers." Also, "*Deleitaos con las embriagadores flores que están en nuestras manos*." (I, p. 50). "Delight in the inebriating flowers that we hold in our hands." We further learn that the propriants encircle their throats with garlands of these flowers, recalling ancient Egyptian practices employing water lilies in a similar fashion.

Wasson, in reviewing the above in a fuller context involving his own thoughts regarding these verses, deduces that the flowers are "the inebriating mushrooms or morning-glory seeds". I would suggest that at this point no evidence has yet been adduced as to the specific nature of the flowers, but to state that "flowers" is a metaphor, and that "inebriating" is not a metaphor is taking liberties that go beyond poetic license. Likewise, Garibay's verses include the mention of *hongos* or mushrooms, and had these been intended, the texts would have so stated. The only argument to this can be that the poet was concealing the essential nature of *flores*.

On page 86, Wasson revises Garibay's translation of "*Brotaron las flores, Abren sus corolas ante él que da vida*." (II, p. 113). "Flowers spring forth opening their corollas before the lifegiver." The revision of Wasson interpolates after the word forth, "like chicks from the egg". Although there are no corresponding words in Garibay's translation, a new sense has been imposed. This would seem unnecessary were it not to convey a mycological meaning. The emergence of a mushroom from its egg-like origins would lend support to the thesis that *flores* is really a surrogate for *hongos* and, more specifically, entheogenic mushrooms. The argument rests on the Nahuatl verb *cueponi* which Molina (1571) translates as "bursting forth, (1) as a chick from its shell, (2) as a chestnut having been roasted, and (3) as a flower emerging from its bud". Since Molina chose the egg metaphor as his first analogy, Wasson has seized upon this over the opening of a flower. However, the poem goes on to speak of the flowers as "rich fragrant flowers ... bedecked with flowery butterflies" (II, p. 113). This does not suit a mushroom, and the egg and chick interpolation is certainly out of place. One might as easily have used the chestnut example of Molina. The texts require neither of these alternatives. Since it is *flores* that the texts refer to, the logical bursting forth would be that of a flower opening. Many flowers open so rapidly that the patient individual is able to watch this progression. Some flowers literally burst forth as the result of opening until the points of the calyx tips separate. *Nymphaea* species generally open very quickly and close just as rapidly.

In *Poesia Nahuatl* (I, p. 49) "*Se va pintando tu corazón con flores polichromas; pintas tú*" is rendered as "Thy heart is being painted with polychrome flowers; thou paintest ..." *etc*. This recalls the many Maya polychrome vases that have survived with frequent depiction of water lilies. Although these were for the most part Maya vessels of the Classical and pre-Classical periods, they are manifest in the imagery of these pre-Conquest poems. The frequency of the water lily motif far exceeds any imagery that might be interpreted as mushrooms.

In a monologue of Nezahualcóyotl it is stated, "*Hay cantos floridos: que se diga yo bebo flores que embrigan, ya llegaron las flores que causan vértigo, ven y serás glorificado*." (III, p. 11). "There are songs in flower: let it be said I drink the flowers that inebriate, already came flowers causing vertigo. Come, and you will be in glory." Wasson interpolates *poyoma* after *flores* in the text and amplifies his choice by stating that the Nahuatl *poyomatli* was intended to designate *Quararibea funebris*, a tree having fragrant flowers that were mixed with chocolate (*Theobroma cacao*) when it was made into a beverage. The problems with such an interpetation are to be found in Garibay's *History of Nahuatl Literature* (1953; I, p. 181) where we encounter "*... aquellas pores, anelhuayo y raiz no conocen*", translated as "... those flowers prosper, and roots they have not". This same statement is reiterated in *Poesia Nahuatl*: "*hay flores perfectas, hay flores sin raices*" (I, p. 29): "there are perfect flowers, there are flowers without roots". Again in the poems we encounter, "*flores anelhuayo desarraigados*". A further clarification of the nature of these "flowers without roots" is found in the same set of verses on the same page: "*aquí se yergue la Flor Blanca*" (III, p. 39). This is translated as "here stands high the White Flower". Wasson sees these as "fungal growths" as fungi have no roots.

For another interpretation, one might look to *Nymphaea ampla* of that region. It is a flower that is white and fragrant and whose flower buds are able to intoxicate due to their nupharidine content as well as possible apomorphine based upon the aporphine-like compounds isolated by Diaz (1977). An earlier verse (also III, p. 39) indicates that these flowers come from "the region afar where the water gushes forth". This suggests that they are aquatic. With the light of day the white flower bursts forth from its green calyx just as in the verses of the poem. The flower bud is ovoid. If one pulls the flowers from the still waters they have no roots. If they are dug they have a rhizome. This tuberous structure has few roots, but is conspicuous by its form. Why not a water lily instead of mushrooms?

Wasson (1974) records María Sabina chanting the following during her mushroom *Velada*: "Woman (of a) root below the water am I, Father Jesus Christ, tender root woman am I." (p, 61, lines 19-21). Wasson suggests this to be an important area of inquiry for the botanist. Since Diaz (1975) records the use of *Nymphaea ampla* in Chiapas where the rhizome is ingested, and since aquatic plants of medicinal value are few, we might suppose María Sabina invokes the water lily.

If a mushroom were intended in the previous verses, why was *hongos* used by Garibay (II, p. 55): "*He bebido vino de hongos y llora mi corazón.*" The Nahuatl for mushroom in the original was *nanacaoctli*, the suffix *-octli* referring to any inebriating liquor. This is not the *xochitl* or flowers of earlier citations. We need not exclude mushrooms from all of these texts, but neither should we find them where they are not. Since the text specifies a white flower, why should we implicate the tree *Quararibea funebris* (Bombacaceae) whose cup-like flowers are yellow or "dazzling yellow" in the words of Wasson (1980, p. 101).

It is not necessary to select either a mushroom or a water lily in all of these various pre-Conquest verses, frescos, and codices. An example of this is to be found in the famed *Codex Vindobonensis* painted in a Mixtec scriptorium. In a future paper on this volume, I will point out the many instances in which the water lily is found in conjunction with the gods and with water and honey. It is my assertion (Emboden, 1979a, b) that the water lily (*Nymphaea ampla*) played a major role in Maya civilization and was used in this and derivative cultures as a primary hallucinogen. Water, honey and the ubiquitous yeast formed a foaming beverage to which *Lonchocarpus yucatanensis* and *Nymphaea ampla* were added (Emboden, 1979a, b). This same white water lily may be found on the page of the Codex (p. 24) on which Caso (1963) found "entheogenic mushrooms".

On page 24 of this codex, Quetzalcóatl is seen carrying a woman who is "the spirit of the mushrooms" as evidenced by the mushrooms in her hair. Subsequently he faces Piltzintecuhtli, or "Most Noble Prince", who holds a pair of mushrooms. Between the two is a flower supported on a peduncle of seven spheres. Piltzintecuhtli is an alter ego of Xochipilli, the Sun God and Prince of Flowers. In the subsequent scene seven gods and goddesses hold mushrooms aloft. Between the fifth and sixth personages we see the same spheres mentioned earlier, but five in number, surmounted by a flower bud that is elongate, or in the terminology of Rands (1953), "mammiform". It is noted by Wasson that this fifth figure in a series of deities holds but one mushroom. Is it the *Nymphaea* but that completes the iconography?

Wasson's commentary on this page stops with his description of that which he interprets as a "mushroom *velada*". I would not take issue with any of this interpretation, but I would like to extend it by finishing a description of that same page. Below figure seven is the *Nymphaea* bud on a knotted peduncle. Rands (1953), in his extensive examination of water lily motifs and their frequency in Maya territory, noted that the knotted peduncle was always associated with an especially significant religious rite. I would suggest that this same contextual use applies here. Just below this is the water lily bud and the five knotted spheres, and to the left is a lake and a diver. Below the aforementioned knotted water lily and bud with spheres is the same motif repeated, and to the left there is a confrontation of two deities. They are able to walk on the surface of the water. The figure to the right holds upright three water lily buds as a sort of emblem of power, much as in ancient Egypt (Emboden, 1979a). Underneath the water there is a knotted water lily with a green peduncle and white flower. Although Wasson does not reproduce this page in color, I have referred to a fascimile edition in color for this verification. On this page mushrooms are united with the water lilies in a divine context just as they are found in a divinatory context among the Maya.

An interpretation of the murals of Teotihuacán occupies Wasson's attention in chapter 8 of his book. The labyrinthine buildings are, in Wasson's thesis, cenacula where small groups of pilgrims might undergo ritual activity. While Wasson suggests mushrooms, morning-glory seed, *cacao* and *poyomatli* flowers as elements of the divine office, there is no mention of the water lily. I presented these murals and discussed my interpretation with Wasson in the Spring of 1979 and yet no mention is made of my interpretations. Yet, Miller (1973) is castigated for not mentioning the publications of Wasson and Heim. For this neglect he is (Wasson's words) "certainly not at home in botanical iconography nor the entheogens". Wasson asserts further that if Miller had read and remembered an article that he wrote in 1957 "his text would have been utterly different". My rather lengthy 1979 discourse with Wasson is relegated on page 158 of his text to "Some have suggested that it [referring to the green mushrooms in his interpretation] might be the leaf of a water lily." After a few terse sentences that do not meet the arguments presented to him, this hypothesis is dismissed as "mycophobia". I would have expected a citation of the person who had made the identification of water lilies in the murals of Teotihuacán. In my defense, I must state that I do not harbor mycophobia; to the contrary, I have eaten numerous genera and species of mushrooms of both the old world and the new world. Yes, I have enjoyed the entheogenic experience of *Psilocybe cubensis* (formerly *Stropharia cubensis*). I will then present my interpretation of these murals as they were set forth to Wasson in 1979.

On a wall of a structure called Teopancaxco there is a mural that is reproduced as Fig. 2 on page 157 of Wasson's 1980 book. It must be remembered that most of the border of this mural had disappeared at the time of its discovery and a copy of an authentic fragment is reproduced as Fig. 1 on page 156 of Wasson's treatment. Accepting both figures as accurate representations, I find alternating peltate leaves of *Nymphaea ampla* and the flowers and flower buds of this aquatic, fresh water plant. The figures that Wasson sees as green (for holiness) mushrooms, I see as the peltate leaf of *Nymphaea* with its serrate margin. The third and the fifth glyphs of the original border (Fig. 1 in Wasson) are interpreted by Wasson as bivalves or snails, the former being the prevailing opinion according to the author. It is very easy to see that the entire scene is aquatic. Snails and bivalves are not found on a stipe - in this border all elements are stalked. If one views these as *Nymphaea* flowers subtended by a tripartite calyx, there is no problem of interpretation. Each flower alternates with a peltate leaf in which the petiole attaches to the center of the leaf in an umbrella-like fashion. Traces of green paint remain on the original leaves of the border.

Wasson suggests that if these peltate images were water lily leaves they would exhibit "a deep cleft where the stem (petiole) leads off". In nature, I respond, the leaf does not exhibit this in so pronounced a fashion as to attract attention to this particular feature. On dried herbarium specimens this aspect of the leaf becomes exaggerated. I would ask why these should be identified as fungi when the presumed "gills" do not emanate from the stipe (petiole) but are mere abbreviated marginal slashes and are not present at all on the sixth image reading Fig. 1 from the top to the base. How is one to explain the calyx of the third and the fifth images? As in the stylized presentations in ancient Egypt, they are tripartite. What basidiomycete is green and aquatic? As a metaphor green is for holiness and is sanctified by its association with water, according to the Wasson interpretation.

It is puzzling to encounter the statement that those who suggest a water lily (Emboden, obviously) "do not suggest a species and are idly guessing". This is misleading, for it was *Nymphaea ampla* that I suggested to Wasson on April 6, 1979, in Nash Hall of the Botanical Museum of Harvard University. I also showed slides of this plant. It is even more curious then why he should present, in Fig. 3 of his text, *Nymphaeu tuberosa*, a water lily that was not mentioned and which does not have the characteristic serrate margin and has not been linked to ritual use.

It should be mentioned that the repetition of the *Nymphaea* leaf and flower, or its bud, was common in Maya presentations and was well documented by Rands (1953). It is this same alternating series that is seen in the *Codex Bourbonicus* (Hamy, 1899) in the figure of Tlaloc, the god of rain, rivers, lakes, etc., reproduced in the Wasson tome as Fig. 4. However, in this presentation of some one thousand years later, the alternating images are at the tips of tributaries or waves and are so stylized that they could be identified only by conjecture. We should deal with primary sources that are revealing rather than secondary motifs that have lost any true identity. The deterioration of symbols is easily seen if one compares the Teopancaxco mural (Wasson's Fig. 2) with the devolved version in the *Codex Bourbonicus* (Wasson's Fig. 5). I cannot see the transition of the latter to Fig. 6 in which an image from the post-Conquest *Atlas* of Diego Duran shows a lake with margins on which there are nine small concentric circles. These appear on many aqueous motifs in the surviving codices as foam on water. Must we force our imaginations to extend these to mushrooms?

Turning our attention to another area of Teotihuacán, all may judge the magnificent mural of the complex of Tepantitla restored by Augustin Caleti on exhibition in the Nations Museum of Archeology in Mexico City. I, like so many others, have had the great pleasure of studying this restoration repainted by the skilled muralist Villagra. Fortunately, Villagra carried out his restoration almost twenty years before any discussion of entheogenic elements in the mural was initiated.

In the upper part of the primary mural of Tepantitla there is a massive deity that Kubler (1967) has taken to be a female divinity. Above her head is a giant flowering tree. To the right and to the left of this deity are hierophants from whose hands water pours into the great lake upon which the scene is resting. Along the margins of the pouring water we again encounter what Wasson identifies as "alternating shells and mushrooms", and which I take to be water lily leaves and buds. Note again (Wasson's Fig. 10) that the leaves are green and the margins are serrate. There are no gills extending to the pileus as is true of basidiomycetes. These aquatic elements are all stalked.

In the lower register of the aforementioned mural is a depiction of "Playing Fields of Paradise" (Caso, 1942, pp. 127-136). While the reproduction in Wasson (1980) is not as fine as that reproduced in Heim and Wasson (1958) we can see a sacred lake in the lower right in which a giant frog or toad is surrounded by "shell and mushroom", according to Wasson. I would point out that there are no indications of gills, only the conspicuously serrate margins. Of the three sets of water lily leaf and flower bud pairs, I would call attention to that in the lower right near the toad or frog's anal area. The leaf has a very decided cleft. That same cleft was stressed earlier as negative evidence by Wasson. He does not call his reader's attention to this portrayal. I would agree when he states that this is "the real world of the entheogenic vision". But, I would suggest that it is the narcotic water lily that engenders the visionary experience.

Details in Wasson's Fig. 13 and 14 further establish the green water lily leaf with its serrate margin emerging from the mouth of a jaguar. I would refer the reader to Thompson (1972) for a discussion of the relationship between the jaguar and the water lily in *Commentary on the Dresden Codex*. An even greater amplification of this is to be found in Coe (1973) *The Maya Scribe and His World*. There is so intimate and regular a connection between the water lily and the jaguar that Coe uses the term "Water lily Jaguar" to identify that deity. While Tepantitla is not Maya, the same associations are to be found. As for the detail in Fig. 14 of Wasson, we see amphibians that are imperfectly developed (metamorphic) swimming with water lily leaves and buds (mushrooms and shells?) in their mouths. Interestingly, there is at the base (center of Fig. 14) a leaf and two buds with feathers emerging from the leaf. In Maya portrayals, it is common to find the flower with quetzal bird feathers stuck inside the corolla. This is regularly seen when a figure of great power wears the flower on his brow (Emboden, 1981).

In a structural complex known as Zacuala there is to be found a mural of the sacred lake in which there is a "radiant mouth". This motif is what Hasso von Winning (1949) has called the "vagina dentata" motif. From the four comers of the sacred lake there emerge four peltate, serrate, green water lily leaves that are called by Wasson "unmistakable greenish mushrooms". Figure 21 of Wasson, which is a painting by Mendoza of a reconstructed bowl from Zacuala, shows the same repetitive motif that has been argued throughout this paper. It is a frequent Maya theme (Thompson, 1966, p. 61).

From my own experiences, I have found that mushrooms with entheogenic properties are superior to any water lily species in provoking the sensation of ecstasis, literally liberating the soul from the body. I do not doubt for one moment that Wasson's research on hallucinogenic fungi is collectively some of the most important ethnobotanical research produced in this century. Much of his recent book is translated from his earlier work with the late Roger Heim and appeared only in French in editions from the Natural History Museum of Paris. There are, however, many new revelations given to us in *The Wondrous Mushroom*. I have initiated this paper on the basis of my personal conviction that, in the instances that I have cited, identifications made by Wasson are not correct. Both Wasson and I are making interpretive assertions, and only readers familiar with hallucinogenic fungi and water lilies will be able to make a decision as to which arguments are most compelling. Only through hypotheses and challenges to these are we going to have an accurate view of the essential activities of the ancient peoples of Mesoamerica.

It is my belief that we do not have to decide whether to accept a fungus or a water lily. Both figure prominently in the literature and iconography of priestly castes in the pre-Conquest period of Mesoamerica.

1. The Beginning

Where does one start to tell the story of the legendary Herb of Immortality, after all there are no living eyewitnesses of this momentous ancient discovery? All the knowledge we have concerning the ancient mystical Herb of Immortality is now found in ancient stories, some of these stories are today considered religious truths by active religions. Other stories are ancient myths of religions now considered extinct. While still other stories are now considered folk tales and fairytales with which we amuse our children; and in doing so, pass these stories down countless generations.

Modern people put their knowledge into books; the ancient people on the other hand placed their knowledge into stories. Some ancient stories are in fact very detailed books of knowledge concerning the Herb of Immortality, when the story is properly decoded a wealth of practical information concerning this unique life form can be rediscovered by a modern person.

While I cannot give you exact information on the ancient discovery of the Herb of Immortality, I can give you some background on how I came to understand the knowledge contained in these ancient stories.

As a young American child, I was exposed to many of the same stories you were as a child. Now some of these stories were completely baffling to me in that they didn't make any logical sense. It wasn't the fairytale bedtime stories that were so illogical, after all, no one, not even a child expected these stories to make sense. It was the other class of stories, the Santa Clause and most especially the Jesus stories that I had the most trouble trying to understand logically.

The Santa Clause story was just baffling from a logistical viewpoint of making and then delivering the Gifts, you know around the world making millions of stops all in one night. Why, those reindeer would have to travel at the speed of light. This Santa Clause story was however nothing compared to the completely baffling Bible story of the man-god called Jesus Christ because the Santa story was always being told kind of tongue in cheek, the Christ story instead was presented to me as not only true but the ultimate truth.

Now this Jesus Christ story was so completely unbelievable to me that I just couldn't get my skeptical little mind to wrap around it. After all, the story starts with the birth of a man supposedly created without intercourse and born from a virgin. Now as a young country boy, I knew the mathematics of animal and human reproduction at a young age and that no person could be immaculately conceived, so the story starts out completely unbelievable to me. Next he turns ordinary water into a superior wine in the first of many miracles, then he miraculously heals the sick, the blind see and the lame walk, yet the Sunday school teacher couldn't explain to me how he did it, it was a miracle and as such could not be explained. Later in the story he is a prophet and can tell or predict the future, again with no explanation given as to how he did it. Then there is his death and resurrection in the flesh in three days; again something that totally goes against logic and nature, since no human who is truly dead has ever rose up again. After his resurrection he is immortal in the flesh and ascends back to heaven where he came from, thus ending the story.

Now this Christ story is very strange but there were other strange things taught in Sunday school that just did not make sense; like my Sunday school teacher saying that the Christ of the Christians was the ancient Hebrew God of the Old Testament bible. I tried for weeks to figure that one out. The Communion was another strange thing since we were supposed to eat the flesh and drink the blood of Jesus, like a bunch of cannibals; luckily all we really had to consume was a little cube of white bread and a shot of grape juice.

I think I was about ten when I just completely gave up trying to rationally understand the Christ story and became a non-believer in both the story and the Christian faith as containing any kind of real truth.

Over the next few years I experienced a growing spiritual hunger and decided to study some other religions to see if they had anything real to offer or if they were just as insane as Christianity. My mother had bought a complete set of 1898 edition Encyclopedia Britannica at our local library's book sale. In 1969 when I was thirteen I happened to open the Encyclopedia at an article on Hinduism and I came across this quote about an ancient plant god named Soma from the Rig Veda; the oldest collection of books in the Hindu literature.

Rig Veda "Book 8 hymn LXVIII"

"1. This here is Soma, never restrained, active, all conquering bursting forth, a Seer and Sage by sapience.
2. All that's bare he covers over; all the sick he medicines, the blind man sees, the cripple walks."

This quote completely "blew my mind" as you would say in 1969; here was a real plant worshiped as a god, that was doing the exact same cures attributed to the Christ. Could it be that the Christ story was about a real plant god and not about a man-god at all?

The next paragraph said that Soma was identical with the ancient Persian Haoma, that it is the Ambrosia and Nectar of the ancient Greeks and that this plant was the ancient and legendary Herb of Immortality. Soma was said to be an Indian version of the Greek God of intoxication Dionysus. However exactly which plant was the real Soma was unknown in 1898.

Since the plant was real there was at last a solid starting point to try and understand these very confusing religious stories. Some checking confirmed that the Rig Veda was far older than Christianity; so Christianity could not have influenced the Rig Veda; in contrast the much older Rig Veda could easily have influenced Christianity.

Research in several dictionaries showed that all the names mentioned in the second paragraph; Soma, Haoma, Ambrosia, Nectar and Dionysus are Indo-European words, meaning that they all belonged to a specific language family called Indo-European. The individual meanings of these names are unique; Soma/Haoma means the pressed one, from the pounding or pressing in the Soma Ceremony while in Greek Soma means the "body". Ambrosia or Ambrose means "not mortal", Nectar means "Death overcomer", these are very strange names for a plant.

In researching for the true Botanical identity of the Vedic Soma plant, it quickly became apparent that nobody knew what plant really was the true Soma of the Vedas. A great many plants were proposed as the real Soma such as Poppy (opium), Cannabis (hemp, pot), Ephedra (amphetamines), and several plants used in India as modern Soma substitutes that are not known to have any mental or healing effects and appeared to be chosen for their small size, lack of leaves and milky sap.

Some of the strangest plants considered as the real Soma are Rhubarb and Ragweed, Rhubarb was proposed because it had red or golden stems and Soma was said to be either red or golden, Ragweed was considered simply because its scientific name is Ambrosia.

It was also proposed that the real Soma was actually a mixture of several plants, but this didn't seem to fit the Vedas description of Soma as the pressed one (singular), not the pressed ones (plural).

Alcoholic brews such as mead and beer were also proposed since Soma is called honey in the Vedas and the grain barley used in modern beer brewing is mentioned as being used in the Soma ceremony. However alcohol didn't seem to match the descriptions of Soma's mental or healing effects, after all, no one today expects the blind to see or the lame to walk from drinking a beer. The Soma Ceremony was at most three days long; hardly enough time for alcoholic fermentation to occur. The Soma of the Vedas was a plant that grew on mountains and was picked and dried, a process completely unnecessary for yeast fermentation.

In studying the Persian version of Soma called Haoma I came across this little gem in an earlier edition of the Encyclopedia Britannica that showed that I was probably on the right track as far as the relationship of Soma and the Christ. This the exact same quote I found in the early 1970's, but quoted here from a later edition.

The following is from the Encyclopedia Britannica (1991, vol. 26, pg. 789, Rites & Ceremonies):

"In Zoroastrianism haoma (Sanskrit soma, from the root su or bu, 'to squeeze' or 'pound') is the name given to the yellow plant, from which a juice was extracted and consumed in the Yasna ceremony, the general sacrifice in honor of all the deities. The liturgy of the Yasna was a remarkable anticipation of the mass in Christianity." "Haoma was regarded by Zoroaster as the son of the Wise Lord and Creator (Ahura Mazda) and the chief priest of the Yasna cult. He was believed to be incarnate in the sacred plant that was pounded to death in order to extract its life-giving juice so that those who consumed it might be given immortality. He was regarded as both victim and priest in a sacrificial-sacramental offering in worship. As the intermediary between God and man, Haoma acquired a place and sacramental significance in the worship of Mithra (an Indo-Iranian god of light) in his capacity as the immaculate priest of Ahura Mazda with whom he was coequal. The Mithraic sacramental banquet was derived from the Yasna ceremony, wine taking the place of the haoma and Mithra that of Ahura Mazda. In the Mithraic initiation rites, it was not until one attained the status of the initiatory degree known as 'Lion' that the neophyte could partake of the oblation of bread, wine, and water, which was the earthly counterpart of the celestial mystical sacramental banquet. The sacred wine gave vigor to the body, prosperity, wisdom, and the power to combat malignant spirits and to obtain immortality."

It should be pointed out that Zoroaster would have to be an exceptional prophet to anticipate the Christian mass since he died approximately 600 or more years before the earliest Christian mass was held. Again we have a situation were the far older Yasna could not have been influenced by Christianity, but early Christianity could easily have been influenced by Zoroastrianism. You will notice that Haoma like the Christ is also considered the Son of God, the chief Priest of the religion and is both a sacrifice and sacrament central to the religion.

It is well known that Mithraism, which was very widespread throughout the late Roman Empire, had a profound impact on early Christianity with Mithra's birthday, Dec. 25th adopted by Christianity as Christmas or Christ's birthday and the adoption of Mithra's day of the week, Sunday as the day of worship and rest, instead of the Hebrew Sabbath of Saturday. The sacred wine of Mithra was a type of Haoma not alcoholic wine since it was said to posses exceptional properties compared to ordinary wine. It is reasonable to believe that the original Eucharist wine of early Christianity was identical to the Mithraic wine.

However, researching Haoma really didn't throw any light on the identity of the real Soma/Haoma plant since many of the same plants were proposed for Haoma as for Soma.

Researching Ambrose and Nectar yielded little practical information on the real plant other than it was considered the food of the Gods, bestowed immortality on humans and according to Homer in the Iliad, the Ambrose/Nectar plant could spring up instantly at the command of the gods.

In 1974 I read a book called "Soma: Divine Mushroom of Immortality" by Mr. Wasson who proposed that the original Soma was the mushroom called *Amanita muscaria* or more commonly the Fly Agaric. This is the large red or gold capped white mushroom with small white warts scattered across the colored cap surface. His was the most convincing argument concerning the identity of the original Soma plant and I quickly came to believe that his identification was indeed the correct one. *Amanita muscaria* was even known to produce psychoactive urine in the users just like the Vedic Soma, a property that no other Eurasian drug plant is known to produce.

Convinced that Mr. Wasson was right I decided to gather as much knowledge as possible in three distinct areas of research. First it was very confusing to have pieces of the puzzle scattered from Greece thru Persia to India, so I decided that understanding the earliest movements and history of these people may provide the background needed. Since Soma/Haoma, Ambrose and Nectar were all very ancient Indo-European words; I began to study the Indo-European languages and history in an effort to try and understand why this magic plant seemed to be everywhere. Second I decided to study the old religions of the Rig Veda, the religion of Zoroaster, the Bible and the ancient mythology in an effort to better understand the relationship of these religions to one another. Thirdly the medicinal benefits of this plant to modern mankind could be of vast importance so understanding the actual plant's natural history and subjecting it to experimentation would sooner or later have to be done.

Keep in mind that I was only 18 when I decided to start this branch of research and life very quickly intervened, so for many years this research was carried on as a very part time hobby.

About ten years into this research I was beginning to understand that the most important parts of the Christ story were the parts that were completely impossible for a man, since these impossible story elements were actually describing the Soma plant.

An awaking for me occurred at about this same time when I walked into a large library and noticed that the real books like how to books, dictionaries, encyclopedias, technical books, science and math etc. were out numbered at least 5 to 1 by fiction books. At that point I began to understand that there were very good, even overwhelming odds that the whole New Testament was a manufactured story and not as many Christians believe a true and historical document. In other words the New Testament was most likely a work of "historical fiction" with real knowledge of the Soma plant purposely encoded into it.

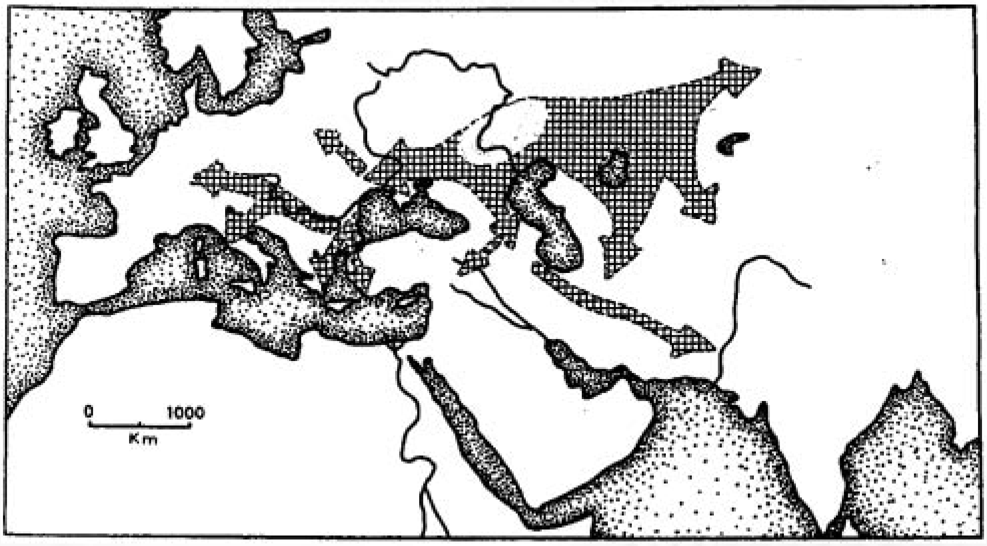
Over the years I have discovered that much of the ancient Indo-European mythology is constructed in exactly the same manner and contains a wealth of hidden yet practical knowledge that is only revealed when you understand that the story is really about *Amanita muscaria*.

2. The Indo-Europeans

It is not the purpose of this chapter to go into an in depth study of the Indo-European peoples but simply to give you some background to help you understand why the religions based on the Herb of Immortality are found so widely distributed over Eurasia. The reader is encouraged to study the Indo-European peoples and history in much greater detail and depth, since for many readers with a Eurasian heritage; they are your ancient ancestors.

The term Indo-European properly describes a very large language family, which includes English, French, Latin, Greek, Gaelic, Iranian, Hindi, and Sanskrit to name but a few. Historically this language family was found from India to Ireland hence Indo-European.

All of the Indo-European languages are descended from a common ancient ancestral language now extinct called Proto-Indo-European. Since all Indo-European languages share a common ancestor and in many ways are still very similar to each other, it is the common belief of language experts that about 7000 years ago all the Indo-European speakers in the world lived in a relatively small geographic area that is believed to be north or northeast of the Black Sea.



(Map: the white oval area is one of the proposed homelands while the other is just west of it N of the Black Sea, the arrows show the routes of the expansions into all the surrounding territory.)

During this time it is believed that the Proto-Indo-Europeans were the first people to domesticate the Horse for riding. There is also archaeological evidence that these people began an extensive development and use of the wheel for carts and wagons, this technology of greatly increased mobility is believed to have been part of the reason for the Indo-European expansion.

Beginning about 6000 years ago there is an expansion of Indo-European speakers out of this homeland East into the Steppes of central Asia and West into central Europe.

Approximately 5000 years ago there is another expansion into Mesopotamia, Persia, Europe and eastward deeper into the Steppes.

About 4000 years ago there is a major expansion from which most of the modern Indo-European languages are descended; this expansion extends the Indo-European languages over a vast area of Europe, the Middle East, central Asia, Northern India, and the Siberian Steppe to Manchuria.

Less than 1400 years ago the rise of Islam spread the non Indo-European Arabic language over much of the formerly Greek and Persian speaking areas of the Middle East and North Africa.

Beginning about 900 years ago the movement of Mongol and Turkish tribes greatly reduces the number of Indo-European speaking tribes on the steppes through warfare, genocide and assimilation, and eventually splits the Indo-European language continuum by the invasion of what is now called Turkey, where the Turkish language replaced Greek.

Within the last 500 yrs with the Age of Discovery there is an expansion of Indo-European speakers into the Asian Steppes, Siberia, North and South America, India and East Asia, Australia and Africa.

About 200 years ago European explorers bring back to Europe ancient writings from India such as the Rig Veda, and the Yasna from Persia, both of which were unknown in Europe at the time.

Language scholars quickly discovered that Sanskrit and ancient Persian were closely related to Latin and Greek and the study of the Indo-European language family was born.

Presently, one half of the world's population speaks an Indo-European language as a first or second language.

3. The Ancient World

In order to understand the ancient stories about the Herb of Immorality you must first understand the differences between the modern world you live in and the ancient Eurasian world. These ancient stories were created in societies whose world view is entirely different than your world view, so it's important that you begin to understand the ancient world view that these stories originated in.

The first major difference is modern people go to the store for the things we need, in fact most people in the west today are absolutely dependent on the stores. In sharp contrast our ancestors lived in the store, from the forests, fields and streams came everything they used and it was Nature that they were dependent on for food, clothing, housing, medicines, and all the necessities of human life. As a rule Primitive people generally know every plant and animal in their environment and how to use them if there is a use for them. Many ancient Eurasian societies contained healers who were masters at using drug plants for medicine. They did this without the knowledge we now posses of the chemistry involved, since it was only in 1806 that a brilliant chemist isolated morphine from opium and forever changed our view of how these magic plants actually worked.

The perspective on the world at large of the modern person is completely different than the ancient world view of the universe. The relatively recent invention in the 1600's of the telescope and the microscope changed a world view that had existed basically unchanged for thousands of years, and expanded the modern universe millions of times over the old world view. When you look up into a starry night sky you know that some of these stars are trillions of miles away, to the ancients the Sun, Moon, Planets and Stars were only a few miles away, and things like Comets scared them since they were believed to be so close.

The Microscope expanded the world view in the opposite direction and radically changed our idea of Nature and our ideas about our own physical body. It has revealed the causes of many diseases and the cellular miracle of all living Creation. To the ancients all of this was completely unknown with things like diseases being given a supernatural cause i.e. Demons, witchcraft, etc or vague natural causes like poisoning, bad water, food or air. The ultimate secret of how plants, animals, and people reproduced themselves was also a great mystery to the ancients who depended on the mysterious fertility of plants, animals, and themselves for their own existence.

Another basic difference between the ancient and modern worlds is how Deities or God(s), are conceived of, in the ancient world only those things that could be seen by the human eye, that were also physically "immortal", and were of use to, or frightening to mankind, like the Sun, Moon, Earth, Sky and Fire were considered "Gods".

In the ancient Indo-European theology the God of "heaven" was the Sky Father, Latin; Ju-piter (Jupiter), Greek; Zeu-pater (Zeus), Sanskrit; Dyaus-pita, Proto-Indo-European; Dyeus-pater and the Germanic God; Tues, as in Tuesday. The ancient peoples Sky Father is the same Sky you see everyday, a sky that brings sunshine, rain, wind, tornadoes, hail, thunder, lightning, flood or drought, and the occasional solid rock we call a meteorite. The sky father was a benevolent deity most of the time but he could also be very destructive, even a mass killer of men. The ancients were very aware of this destructive side of the Sky Father and always wanted to be on the good side of the Sky Father. Unlike the modern world there were no ancient atheists since everyone could plainly see the Sky Father, and only an idiot would have claimed the Sky didn't exist.

In contrast the modern world view has destroyed the ancient Gods of Sun, Moon, Earth and Sky. Since a visible or real "God" no longer has a place in our physical universe, modern people only have "supernatural" Gods. These modern concepts of an invisible God are of course our way of keeping the ancient Sky Father alive in our minds and societies long after we dethroned him and destroyed his heaven with our science.

Modern people have to always remember that the Gods of the ancient people are always real things; and that the stories about these real Gods are describing something real.

Now if we blindly assume that the ancient's concept of God was the same as our modern concept of a supernatural god then everything the ancient stories say about these real Gods, will always be misinterpreted by us, with the result being that we will fail to understand the real wisdom contained in these ancient stories about these real things.

Another very important thing to keep in mind is that the ancients always personified these real Gods in their stories; so if you naively believe the story is about the "person" in the story and do not know its about a real God/thing personified you can mislead yourself into a supernatural wilderness were absolutely nothing is real. A wilderness were confusion, illusion and misunderstanding rules all and reason can not be found.

4. Amanita muscaria - Legendary Herb of Immortality

The ancient Indo-Europeans called the *Amanita muscaria* mushroom "Maga" (The Great Gift) and so great was this Gift that its fame and name echoes down the ages as the root of our modern word Magic. The "Magus" or "Magi" (Great Gift bearers) used this truly wondrous great Gift of Nature; that healed their bodies of sickness and inspired their minds with wisdom and poetry, and they praised it in story and song, even worshiping the Gift as a God, it being the only source of an incredible magic.

The great Gift bears hundreds of different ancient names; the Greeks called it "Ambrosia" (Not Mortal) the "Nectar" (Death-overcomer) of the Gods. As the ancient legendary "Herb of Immortality" the Great Gift alone holds the Secret of what we call the "Holy Grail" and the magic multiplying "Living Bread" of the New Testament Bible.

The Great Gift is incredibly old, far; far older than mankind and in its original discovery by ancient western man are the roots of our western magic, religion, science and medicine.

The Great Gift has worn many names of Gods such as the Indo-Aryan's "Soma" with 100+ names the drinkable Immortal Living God who made the "blind see and the cripple walk" thousands of years before any human named Jesus walked the earth. Soma was so revered that Bronze Age "Seers and Sages" composed over 100 Hymns in its honor; these Hymns ring with ecstatic praise of this divine Living God, and are incorporated into one of the world's oldest religious text, the Rig Veda.

"Haoma" with 50+ names, the Persian pronunciation of Soma was the sacred drink made from a sacred immortal plant, which inspired the Persian Prophet Zoroaster to create a new religion that in approximately 550 BC became the state religion of the ancient Persian Empire, which stretched from the Nile in Egypt to the Indus river of India.

Zoroaster's religion had a tremendous impact on what we would call the Old Testament Hebrews who were a part of the ancient Persian Empire and who's Prophets like the Persian Prophets (Magi) rehydrated the dried fungus and pressed out a magic Elixir or used it to create the Living Bread and by its power they healed the sick, found lost objects and foretold the future.

The Hebrew Prophets called this one wondrous life form by more than twenty names including "the Anointed One" which in Greek is "Christos", Latin "Chrestus", English "Christ".

The New Testament story of the Sky God's divine infant's "virgin birth", who "turns water to wine", then "heals all the sick", who is "the source of all prophecy", that suffers death at the hands of men only to "resurrect in three days" and then became "Immortal", a story that is totally impossible for any man, yet it is exactly those impossible elements of the Christ story that are actually an accurate description of the birth, use, and death defying ability of the ancient Sacramental "Herb of Immortality".

The legendary "Herb of Immortality" the source of the golden, honey sweet, "Elixir of Life", the goal of philosophers, alchemists and mystics alike, who quested after it in the hope of life eternal. This theme of human immortality from consuming a very special Herb of Immortality is found throughout Eurasian mythology and in the ancient texts that are the foundation of several modern religions "Soma" in the Rig Veda (Hinduism), the "Fruit of the Tree of Life" in the Old Testament (Judaism and Christianity) and as the "Eucharist" or "Christ" in the New Testament (Christianity). All of these ancient texts also mention the same basic "Miracle" cures "the blind see, the deaf hear, the lame walk, and all the sick are cured" and greatly extended life spans for those humans who regularly consumed this magic herb.

However a close examination of the name or phrase "Herb of Immortality" and related words in the context of the ancient texts that refers to it, reveals that the ancients who actually used and knew this "plant" had a much more literal meaning of immortal in mind, when it is applied to the actual "plant".

The prefix im - when used in English means "not" as in impossible = not possible, or improbable = not probable. Mortal in English means "death" so the word immortal literally means "not-death" this is the same concept we see in the original ancient Indo-European words, where A= not, such as Greek, Ambrose = not-death, ancient Persian, Amarta = not-death, and Sanskrit, Amrita = not-death, or deathlessness. All of these ancient words are names of a "deathless plant" that produced a living magic drink with the same name; i.e. Ambrose, Amrita, and Amarta are all names of the plant and the drink made from it. "Herb" in English is traditionally considered to be any species of non-woody plant picked for medicinal, culinary or aromatic use. Keeping in mind that from ancient times until just very recently mushrooms were always considered to be "plants" since they are obviously not animal or mineral. When you place the two concepts together you end up with the "herb of not death" or the "herb that is not death," so it is the "herb" that is "immortal." This Herb's real physical Immortality is the true Secret of the Holy Grail and the Bibles Living Bread.

We know this life form today by its scientific name *Amanita muscaria* or its common name the Fly Agaric, it is the large golden or red-capped white mushroom with small white flakes on the cap that is commonly found in temperate forests worldwide. The names *Amanita muscaria* and Fly Agaric both refer to this mushrooms ability to attract, intoxicate and completely stupefy housefly and other fly species, along with slugs, snails and beetles, please note; removing these comatose insects and slugs from the mushroom usually results in their complete recovery within the hour.

Amanita muscaria is commonly considered poisonous to humans, yet reliable recorded fatalities are extremely rare, even when it is consumed fresh in large quantities by humans seeking intoxication or even those attempting suicide, however the resulting experience is usually not one many people would repeat.

Drying the fresh *Amanita muscaria* mushroom at a low heat of 100-120 deg. F until it is completely dry radically changes the mushrooms chemistry leading to an aromatic, sweet tasting form that is usable, storable, and resurrect able. Consuming this dried form is capable of generating a profound fundamental spiritual experience in some individuals.

While doing field research that led to my first book "The Sacred Secret; The Return of the Christ," I discovered that *Amanita muscaria* resurrects in three days and is Immortal, exactly as the ancients said it was, a very important fact that seems to have been overlooked by both modern Biological Science and Religious scholars. Further research into this natural immortality led to my second book "Natural Magic; Recreating the Grail", in which I show that *Amanita muscaria* is the only logical source of the Holy Grail and other magic vessel legends of Eurasia. In this work I will show that *Amanita muscaria* is the source of the biblical Living bread and the only logical explanation of the miracle of the multiplying loaves.

To understand how a mushroom that is here today and gone tomorrow can really be "Immortal" you have to know what the mushroom *Amanita muscaria* really is.

5. Amanita muscaria - The Fruit of the Trees of Life

All mushrooms are the fruit of a fungus and contain microscopic seeds called spores. Just as an apple bears no resemblance to the tree that grew it, a mushroom bears no resemblance to the fungus that grew it.

Fungi are a distinct branch on the biological tree of life, being neither Plant nor Animal but their own unique type of life form. Fungi are somewhat similar to animal life in that, both Animals and Fungi must find and burn food (carbohydrates) for life energy using oxygen and producing carbon dioxide, unlike green plants, which through photosynthesis can make their own food from water, carbon dioxide and light.

The Fungi are divided in to two broad categories, "Fungi Imperfecti" the simple fungi; yeasts, smuts, rusts, and molds like bread mold, penicillin mold etc. and the "Fungi Perfecti" the mushrooms etc. This division is based on how the Fungi produce and distribute their spores. The Imperfect fungi reproduce by budding (yeasts), or by using simple spore bearing structures to produce their spores and their reproduction usually involves no genetic mixing.

The Perfect fungi instead create mushrooms or other advanced structures to produce and distribute their spores, which are part of a fairly complicated nonsexual type of reproduction involving genetic mixing, which we won't go into here. However many higher fungi can and do make spore bearing structures similar to simple fungi and release spores by this method also.

All Perfect fungi are composed of thread like cells (mycelium) joined end to end and usually can only be seen by the naked human eye when in mass. The tiniest piece of a mushroom fungus, even a single cell of mycelium, can grow into a complete full sized fungus.

Many fungi are Mycorhiza which literally means fungus + root; and have a symbiotic relationship with a green plant; modern research has shown that approximately 95% of all the green plant species on earth each depend on one or more Mycorhiza fungi species to survive! The Mycorhiza Fungi supply their plant partner with water, nutrients and very importantly antibiotics, since green plants have no immune system of their own; in return the plant feeds the fungus carbohydrates.

Many Fungi manufacture and secrete chemicals that are very strong antibiotics; in fact almost all of modern Medicine's antibiotics were first discovered in Fungi.

Perfect Fungi have a unique ability to transport several times their body weight of water through their mycelium per day and it is possible for dried Fungi mycelium and dried mushrooms, to absorb water, and return to life after being completely dried for long periods of time.

Since a living fungus needs to eat; and it has to grow to obtain its food, many Fungi are capable of extremely fast growth of their mycelium. It has been estimated that a healthy mushroom culture growing on grain in a quart jar can grow new mycelium at the rate of 1 kilometer (6/10 of a mile) per 24 hours.

In the case of mushrooms the fruiting body is capable of an almost explosive growth, for example an *Amanita muscaria* mushroom can grow from a little egg smaller than a golf ball to a specimen 10 inches high and 8 inches across the cap in just a few days.

The spores of many Imperfect and Perfect Fungi are capable of circling the globe on the wind and are resistant to extremely high altitude, radiation, cold, heat, and many corrosive chemicals. As a class Fungi are some of the hardiest life forms on the planet and in a very real sense they are Immortal when compared to higher plant and animal life.

An individual *Amanita muscaria* fungus can be a huge organism that penetrates acres of ground, is symbiotic with hundreds of trees, weighs multiple tons, and with a possible lifespan measured in thousands of years.

Amanita muscaria is a Mycorhiza fungus that lives in a symbiotic relationship with certain tree families like Pine, Spruce, Hemlock, Fir, Larch, Birch, Beech, Maple, Poplar, Alder, Hazel, Olive and others. The *Amanita muscaria* fungus provides their trees with water, nutrients, and antibiotics in return the fungi are fed by the tree with carbohydrates and fallen debris such as leaves, needles, twigs etc...

Only with suitable symbiotic trees will the *Amanita muscaria* fungus fruit and produce its mushrooms. This very special relationship of *Amanita muscaria* with these particular trees was noticed anciently and led to the idea of the Tree or Trees of Life that produced the magical Fruit of the Tree of Life. This ancient Fruit of the Tree of Life concept is spread all over Eurasia and is also found in the Genesis story of the Old Testament Bible.

It is interesting that many of the Trees of Life actually named in Eurasian mythology are tree species that do not produce any edible fruit of their own, yet are symbiotic with *Amanita muscaria*, which shows that *Amanita muscaria* is the true "Fruit of the Tree of Life" in these ancient legends.

6. Amanita muscaria - Soma the pressed One And the Holy Grail

Rig Veda; Book IX Hymn LXII 4-8
4. "Strong, mountain-born, the stalk hath been pressed in the streams for rapturous joy: Hawk-like he settles in his home.
5. Fair is the God-loved juice; the plant is washed in waters, pressed by men: the milk cows sweeten it with milk.
6. As drivers decorate a racehorse, so have they adorned the meath's juice for Ambrosia, for the festival.
7. Thou Soma drop, with thy streams that drop sweet juices, which were poured for help, has settled in the cleansing sieve.
8. So flow thou onward through the fleece, for Indra flow, to be his drink, finding thine home in vats of wood."

All of the ancient Indo-European religions contain a variant of the Soma ceremony which even thousands of years ago was considered ancient in origin, some religions ascribing the Soma ceremonies creation to the first man, in others it was the Gods who first preformed the Soma sacrifice. The Soma ceremony is the oldest record we have of the interaction between *Amanita muscaria* and men, for without the Soma ceremony men would have never discovered that *Amanita muscaria* was an Immortal Herb.

In the Soma ceremony the dried *Amanita muscaria* earned the name Soma "the pressed one" by being re-hydrated with water and when it had absorbed as much water as it could hold, it was juiced so to speak, by being pressed or pounded between two stones to release the golden colored Amrita; the legendary Nectar of the Gods.

To filter, this juice was poured onto the high end of a wooden trough set at a shallow angle that was lined with "the eternal fleece," at the other end of the trough the now filtered fluid fell into a large carved wooden vat called the "Drona" (dronakalasa) which was claimed to be Soma's "home," into which was added a cooled, previously boiled thin gruel of water, ground or cracked barley, milk, and honey, this gruel, was then ladled from the Drona into wooden or terra cotta pitchers, poured into individual wooden or terra cotta, beakers or cups, and then consumed, generating a Divine rapturous joy in the participants of the ceremony.

When *Amanita muscaria* is used in the Soma ceremony you end up with a living wooly looking wooden trough and living magic cups, pitchers, and the Drona or vat, which all become "Soma's home". In essence these living cups, are the same as what we call the Holy Grail or the Bibles "Cup of the Lord".

The same *Amanita muscaria* Mushrooms are hydrated and pressed or pounded three times in the Soma Ceremony and are shattered into fragments, the mushrooms are basically gone, however they have released billions of spores and countless microscopic fragments of the mushrooms into the fluid, both of which can come back to life as *Amanita muscaria* mycelium, every drop of this fluid is alive with *Amanita muscaria*.

When this fluid penetrates the porous walls of a new wooden or terra cotta vessel it carries the microscopic spores and fragments with it. The addition of the foods to this fluid gives the fungus an energy source to grow on; in approximately three days the mycelium will be clearly visible to the human eye, and very much resembles white or gray sheep's wool or an old mans beard.

Once the *Amanita muscaria* mycelium is established in a vessel it is in effect a living vessel, the Herb of Immortality now has a new home and a new symbiotic relationship; one with the man whose cup it now lives in. A symbiosis where the *Amanita muscaria* fungus living in the vessel receives food and water, in return the human receives a dose of effective antibiotics and a very unique, profound spiritual experience by consuming the same food and water that was shared with the fungus.

It is this symbiosis that makes the Holy Grail truly "Holy," a Living Vessel that transforms the simple shared food and water into a Communion meal with a Living God.

The influence of this extremely ancient Communion Ceremony on much more recent religions like Christianity can not be ignored, since the Christian Communion where the participants are supposed to eat the body, and drink the blood of a sacrificed yet living immortal god, is truly based not on a last supper in Jerusalem, but on the ancient Soma Sacrifice ceremony.

The "Christ" or more precisely the Eucharist in the New Testament has more than thirty names. It is simultaneously the "Lamb of God", the "Living Bread," a "Living Stone," a "Living God," the "Living Water," the "Resurrection and Life," the "Son of God" and the "Tree of Life."

Some of the most bizarre statements ever committed to writing are in the New Testament Bible, most of these strange statements are attributed directly to the mythological founder, and these bizarre statements have confused true believer and nonbeliever alike ever since. This confusion is the natural result of applying these statements to a "real man," since these same exact bizarre statements make perfect logical sense when they are applied to the ancient Sacramental Herb of Immortality.

7. Amanita muscaria - The Living Bread

Gospel of John 6:48-51
48. "I am that bread of life.
49. Your fathers did eat manna in the wilderness, and are dead.
50. This is the bread which cometh down from heaven, that a man may eat thereof, and not die.
51. I am the living bread which came down from heaven: if any man eat of this bread, he shall live for ever: and the bread that I will give is my flesh, which I will give for the life of the world."

Here we plainly have an ancient reference to consuming magic "bread" that came down from heaven, and that eating this Heaven sent "flesh" will allow a man to live forever. Obviously this can only be a reference to the ancient Herb of Immortality in its role as the early Christian Eucharist.

The ancients always associated the Herb of Immortality with the Sky Father God, since only when the sky flashed with lightning, roared with thunder and rained in season, did these very special Sacred Magic Mushrooms appear on earth. It is this connection of the Sky Father God and the *Amanita muscaria* mushroom that led to the "Son of God" conception for the Herb of Immortality and the ancient idea that the living Herb of Immortality literally came down from Heaven.

Since the *Amanita muscaria* mushroom seemed to appear over night and it has no roots or seeds visible to the naked human eye it was anciently thought that it was "immaculately conceived", "virgin birthed" or as the Rig Veda so eloquently and simply states, Soma is "Born of Thunder".

All most everyone who tastes the dried *Amanita muscaria* mushroom comments on how good it tastes, most people comparing the flavor to honey, malt, or sweet bread, surprisingly no one says it tastes like a mushroom. I find it very interesting that several Roman Catholic people who I have shared the dried *Amanita* Mushrooms with on many different occasions over the years have stated that it tastes just like the "Host" or "Eucharist" the small Sacramental water which is claimed to be the "Body of Christ" used in the Roman Catholic Mass.

At first glance this would appear to be all the information contained in this statement of John, but the name "living bread" is a key to an even deeper understanding of the New Testament's Sacramental use of *Amanita muscaria*. This "living bread" of the New Testament is really alive and the main characteristic of all life is that it multiplies; this ability to multiply reveals that the "miracle" of the multiplying loaves in the New Testament has an entirely natural source, the ancient Herb of Immortality.

The name "the Lamb of God" gives us a clue as to the appearance of this "living bread"; the mycelium of *Amanita muscaria* can be several inches long and resembles white or gray sheep's wool or an old man's white or gray beard.

Living Bread
In this section you will learn how the ancients made the Sacramental Living Bread of the New Testament, and how to duplicate the "Miracle" of the multiplying loaves of Spiritual food.

The ancient technology of the living vessel or Holy Grail can be used to make the "living bread" which greatly increases the supply of this very special Sacrament. In the Grail legends the Holy Grail could create both magic food and drink, at first I thought that this was a reference to the barley gruel of the Soma ceremony, which is both food and drink, but further meditation on the name the "Living Bread" along with a lot of actual experimentation convinced me that simply changing the shape of a living vessel from the Grail's vat, pitcher or cup shape into a shallow bowl or pan to increase the oxygen supply and release excess heat, and changing the food to water ratio from the Grail's mostly water, to a "living bread" formula of boiled grain containing a lot of solid food and a minimal amount of excess water.

When this cooked grain is placed in to a suitable shallow living vessel, it is quickly colonized by the *Amanita muscaria* fungus, which grows into a solid fleshy loaf with the exposed surface, covered in long wool looking mycelium. In usually four to seven days this loaf of fungus can be removed from the living vessel, dried at low heat and used as if it were the dried *Amanita muscaria* mushroom. The living vessel can then be refilled with new boiled grain as soon as the old loaf is removed to start this cycle over again. If the fungus cake is handled properly it can be used to create a much larger quantity of living bread and at the same time create even more magic living vessels, which can produce still more living bread. Some simple calculations based on experiments show that using the right techniques an ancient person could start with a single medium size properly dried *Amanita muscaria* mushroom cap and in less than a month's time create several pounds of dried living bread and at least a dozen small living vessels, this "Living Bread" multiplies very rapidly and can easily feed a fair number of people with the Eucharist Sacrament in quantities large enough to manifest it's dramatic healing effects and allow a profound spiritual awakening to be generated in the participants.

Now you know the ancient Living Secret of Eurasian Magic and Religion; the true Secret of the Holy Grail and the Living Bread; now you can begin to understand the true greatness of the ancient "Maga" the Great Immortal Gift of Nature that just keeps giving it's own flesh and blood and by doing so, heals the sick and inspires human minds with it's unique Wisdom. The stories of the ancients say the Maga may be the Secret to the Greatest Gift of them all, that of an extra long, healthy, and happy life.

8. Amanita Muscaria - The Healing Herb

The Rig Veda; Book VIII, Hymn LXVIII.
1."This here is Soma, never restrained, active, all-conquering bursting forth, a Seer and Sage by sapience.
2. All that's bare he covers over; all the sick he medicines, the blind man sees, the cripple walks."

I came across this quote from the Rig Veda in an old 1898 encyclopedia in 1969 when I was thirteen and the questions it raised completely changed my life, leading me on a life long quest to understand the ancient and legendary Herb of Immortality.

So began my treasure hunt for this miraculous Herb of Immortality, a hunt through all the ancient religious texts and Mythology of Eurasia I could find; and reviewing all the other plant candidates that had been proposed as the original Soma. Seeking to find the one real thing all of these Myths seemed to have in common the "Magic Herb," which since it is real, can be understood scientifically, becoming for me a search for real knowledge of this ancient miraculous healing plant; which may be the single greatest healing Herb on earth.

My own years of hands on research with *Amanita muscaria* convince me that it is the only life form that could be the Soma, Haoma, Ambrosia, Nectar and Eucharist of the ancient religions. Not only is *Amanita muscaria* truly Immortal; it also possesses very strong antibiotic, antiviral properties which we will explore further in this chapter. First we will compare the healings in three ancient religious texts; then we will examine the latest modern biochemical analysis of *Amanita muscaria*, and lastly we will examine evidence from modern people who have been cured of various illnesses by consuming dried *Amanita muscaria*.

The following is from the Sacred Secret
Action after Ingestion of the Soma, Haoma, Christ

The action of a drug in the human organism is fairly constant regardless of cultural differences. For example, Penicillin will cure certain infections in an Eskimo, Hottentot or you. It works the same regardless of culture; it will even work on someone who doesn't believe it will work, because of this fact; this is an even more valid comparison than the two preceding ones. Names are tied to culture and thus subject to variation; the action of a drug or drug plant is not.

The action of the drug plant under consideration has features peculiar to itself. No other drug plant in Eurasia has all the effects of the one under our consideration; this uniqueness means we are not likely to be confused by another drug plant.

The reader is cautioned that this plant is a psychoactive plant. Ancient references to the blind seeing and the lame stepping forth may not be literal, as in the blind see (visions) and the lame steps forth (psychically), but in three different religions there are the exact same references to healing. I believe if this plant were tested, it would reveal very strong antibiotic and antiviral properties, and, surely the ancients knew a healing when they saw one. It will, however, take someone much more qualified than me to test this and discover the truth.

What we hope to discover is the reputed action of the plant in those three different religions. If there are correspondences between the action of the Soma, Haoma and the Christ/Eucharist, a simple chart will reveal it.

14. Psychoactive Urine	X	X	X

X = Clearly stated in Texts.
V = Covered by a general statement, such as the Rig-Veda's statement that Soma cures all the sick.
I = Implied in Texts.

1. General healing, any claim of healing.
2. Both deafness and blindness in the texts may be a spiritual concept, i.e. we are all blind and deaf until the herb opens our eyes and ears, however most hearing loss today is due to bacterial infections, or as complications from a serious illness.
3. The major cause of blindness even today is bacterial infections. A certain type of Bacterial blindness "Ophthalmic blindness" is transmitted by flies and was very common in the Middle East; it is now treated with antibiotics.
4. The major cause of lameness anciently, would be polio, a virus. A plant with antiviral properties may be an effective treatment.
5. Leprosy is cause by a bacterium; the modern treatment is with antibiotics.
6. Makes the old young (Yasna).
7. Several different types of mental illness are described in the New Testament along with what appears to be Epilepsy; all are supposedly cured or helped; the Christ/Eucharist and Soma/Haoma are all said to cast out demons in their respective texts.
8. & 9. Prophecy and prophets appear to be common to any variant of the Herb of Immortality Cult, the fact the herb is the only way to truly prophesy is always stressed.
10. All three agree on a Divine intoxication being one of the effects.

11. Visions, whether part of prophecy or not, are one of the effects. The blind seeing may also be a reference to visions.
12. The voice of the God is stressed in the Rig-Veda's "Master poet never yet equaled" and the New Testament's "Word of God"
13. It is hard to determine what exactly is meant in the texts by immortality and becoming immortal. All three religions stress this as the most important effect of the sacramental herb. "We have drunk the Soma, We have become immortal" Rig-Veda.
14. Psychoactive urine is found in all three texts, and was the conclusive proof that *Amanita muscaria* is the Soma, Haoma, the New Testament reference to psychoactive urine is John 7: 37-38 and is proof that the Christ/Eucharist is also *Amanita muscaria*.

Please note: I believe the only reason the Haoma column isn't a perfect match, is the shattering of the Yasna's texts by Alexander the Great's invasion of Persia, plus my inability to get all of the remaining Yasna texts to compare to the other two.

Once you understand that *Amanita muscaria* is the subject of the most ancient veneration and is the real "Living God" of the Eurasian religious texts preserved from antiquity then the secret of the "Miracle healings" is laid bare.

Diseases; the tiny Demons

Bacteria are single celled life forms of the class Schizomycetes, that can be easily seen under a good optical microscope, most bacteria are completely harmless and some are very useful to man in creating cheese, vinegar, yogurt etc. however many bacteria create disease by infecting green plants and animals including mankind. Some of the most horrible diseases to afflict mankind are caused by bacteria such as Leprosy, Tuberculosis, the Black Death (bubonic plague), Cholera and Typhus.

Recently whole new classes of bacteria have been discovered that are up to two hundred times smaller than normal sized bacteria, and some of these micro bacteria have been implicated in causing human diseases including non rheumatoid Arthritis.

Antibiotics are chemicals that selectively kill bacteria, and many Fungi manufacture and secrete antibiotic compounds to eliminate or control the bacteria in their environment. Modern science has discovered hundreds of antibiotic compounds, mostly in the Fungi Imperfecti; such as Penicillin, the first antibiotic isolated from a Fungi. This discovery has revolutionized Medicine; since common Bacterial infections that 70 years ago were death sentences, are now successfully treated with Antibiotics. Unfortunately Bacteria have a high mutation rate and many disease Bacteria exposed to antibiotics quickly develop resistance to these chemicals eventually making those antibiotics obsolete for treating these bacteria.

The other major class of diseases in plants, animals and mankind are Viral in origin. Viruses can only be seen by using an electron-scanning microscope and are orders of magnitude smaller than bacteria. For a very good example of just how much smaller a Virus is than a Bacteria; we have to think on the larger scale that we are more familiar with; imagine if a single Bacteria cell was expanded to the size of a 747 airplane fuselage, at the same scale a single Virus would be the size of a rat! Viruses consist of a core of DNA/RNA surrounded by a protein case, and can only reproduce inside a living bacteria, fungi, plant, or animal cell. Viruses attach themselves to the outside of the cell membrane and then inject their DNA/RNA into the host cell, once inside a suitable cell the Virus DNA/RNA commandeers raw materials and forces the cell to produce the virus protein cases, while the viral DNA/RNA reproduces very rapidly at the cells expense. A single virus may become several hundred viruses, which then load themselves (the viral DNA/RNA) into the protein cases and leave that cell in search of more cellular victims, the host cell ruptured and depleted of the materials needed to heal it self, dies. Viruses are the ultimate users, the smallest known predators, and a most efficient life form in that it isn't really alive, unless it's looting a cell to reproduce itself. Viruses have a fairly high mutation rate, so a relatively harmless virus can mutate and suddenly become deadly.

Viral diseases include the common cold, influenza, Small Pox, Chicken Pox, Herpes, Rabies, and Polio. Rheumatoid Arthritis is now thought to be a viral disease; and viruses have been implicated as the cause of several Cancers. The latest research has shown that the same virus that causes Mononucleosis (mono) is also the cause of Multiple Sclerosis (MS) a degenerative nerve disease. Many Virus infections live in the nerves of animals where the animal's immune system does not function; including Polio; which leads to paralysis of the infected nerves and the eventual atrophy of the affected limbs; and if vital nerves to the heart or lungs are infected Polio could quickly cause death. According to Archeologists who have studied diseases in the ancient Eurasian people, Polio was the major cause of lameness with Arthritis being the second major cause.

Unlike Antibiotics; Antiviral chemicals appear to be rare in Nature; and many of the Antiviral compounds used in modern Medicine are very expensive and have severe even toxic side effects. Now this apparent scarcity of antiviral agents in nature may have more to do with how we hunt for them than any real scarcity. Most antibiotics come from the simple fungi, which produce them to eliminate the bacterial competition for a limited food supply, finding and testing these Fungi for antibiotic use is fairly cheap compared to testing antiviral compounds.

Animals have immune systems and can deal with most virus infections; green plants on the other hand have no immune system of their own, there is no way a green plant can deal with a bacteria or viral attack. This is one reason the Mycorhiza fungi are so important; they supply their plant partners with antibiotic and antiviral compounds and these compounds keep the green plant healthy.

In the search for effective antiviral compounds the Mycorhiza fungi would be the logical starting place. *Amanita muscaria* is a Mycorhiza fungus that can keep its symbiotic trees alive and healthy for thousands of years. Fortunately for us the ancients did most of the actual field research; in the Holy writings of the ancient Eurasian religions are the clues needed to rediscover an effective antiviral agent; *Amanita muscaria*. The healing of the lame in the Rig Veda, Yasna, the Old Testament, and New Testament are obviously references to healing Polio a known virus.

The third major causes of diseases are parasites, which are single celled to multicellular animals that can range in size from microscopic organisms to intestinal worms several feet long. Malaria is a microscopic parasite transmitted by mosquitoes, which affects humans in large areas of the world. Many parasitic infestations are extremely hard to kill since chemicals that can kill a small parasitic animal are often very toxic to the large animal that is infested.

In nature the *Amanita muscaria* mushroom is often found with paralyzed or comatose insects and slugs in or on the mushroom, this may be a sign that *Amanita muscaria* could cure certain parasitic diseases, but this has not been proven.

The fourth major cause of diseases are fungal infections of which ringworm, athletes' feet, and yeast infections are the most common, however some molds, mildews and other fungi can cause serious illness or death if their spores are inhaled in large quantities or if mold contaminated foods are eaten. It is thought by many Health Professionals that the yeast infection *Candida* is actually to blame for a host of medical problems masquerading as separate diseases.

Some fungi infections can be very hard to combat with the standard antifungal agents in use today. Strange as it may seem some fungi manufacture and secrete potent antifungal compounds to reduce the competition in their environment from other fungi.

There are several compounds in *Amanita muscaria* that exhibit antibiotic action and other medicinal effects, which are known to science.

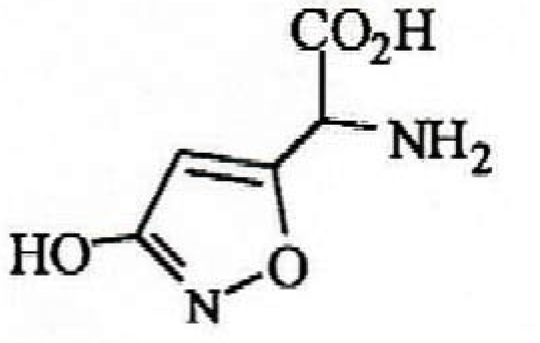
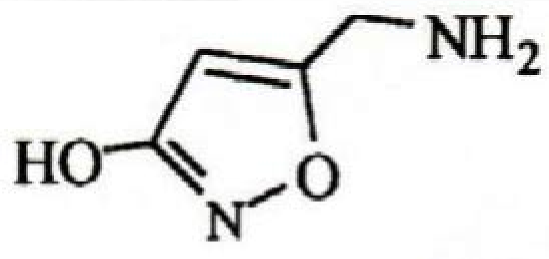
Amanita muscaria: Chemistry, Biology, Toxicology, and Ethnomycology.
By Didier Michelot and Leda Maria Melendez-Howell

"Ibotenic acid, and particularly muscimol, have to be regarded as the substances responsible for the psychotropic action of *Amanita muscaria*. The effects of both substances are similar but not identical to the effect of the fungus in toto."



Ibotenic acid

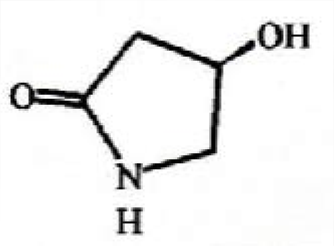
"Ibotenic acid (pantherin, agarin), i.e. a-amino-3-hydroxy-5-isoxazoloacetic acid, is colorless (crystals, C5H6N2O4, mol. wt. 158.11, mp. 150-152 deg. C decomposition), readily soluble in cold water. Any attempt of dehydration leads to decarboxilation yielding quantitatively muscimol."



Muscimol

"Muscimol, i.e. 5-(aminomethyl)-3-hydroxyisoxazole, isolated from *Amanita muscaria*, is colorless (crystals, C4H6N2O2, mol. wt.114.10, mp. 175 deg. C decomposition) readily soluble in cold water."

"Interestingly, cycloserine (myxomycin, seromycin, D-4-amino-3- isoxazolidone) is an antimicrobial tuberculostatic agent that exhibits a similar carbon backbone as muscimol."



(-)-R-4-hydroxy-pyrrolidone-(2)

"(-)-R-4-hydroxy-pyrrolidone-(2), whose structure is closely related to ibotenic acid and muscimol, was found in *Amanita muscaria* (Matsumoto *et al*. 1969a). This chemical frame is common in some micromycetes; they generally exhibit a potent biological activity against bacteria and other fungi (e.g. aureothrycin, equisetin)."

"A; B-(1->6) branched (1->3)-beta-D-glucan (AM-ASN) was isolated from *A. muscaria*. AM-ASN exhibited antitumor activity against Sarcoma 180 in mice (Kiho *et al*. 1992)."

(Sorry; no chemical drawing of AM-ASN is available to me at this time.)

As you can see, the two major chemicals Ibotenic acid and Muscimol found in *Amanita muscaria*, are closely related to known antibiotics. Plus, the chemically related hydroxypyrollidone derivative found in *Amanita* *muscaria* is a known antibiotic and antifungal; also found in micromycetes.

The chemical AM-ASN a Beta-glucan is extremely interesting for its antitumor activity; Sarcoma 180 is a standard cancer cell line that is used in cancer research all over the world. AM-ASN may in fact be the antiviral compound we are searching for but that testing has yet to be performed.

No specifically antiviral compounds are found in this paper; that doesn't mean that they do not exist in the mushroom; it simply means that no research has been done in this area.

This is the basic research on the antibiotic properties of *Amanita muscaria* however there are other medicinal properties that are very interesting concerning ibotenic acid and muscimol in this paper.

"Ibotenic acid and muscimol are respectively conformationally restricted derivatives of glutamic acid and gamma-aminobutyric acid (GABA)."

"Glutamic acid is a major excitatory neurotransmitter in mammalian central nervous systems and its receptors are implicated in neurological disorders such as epilepsy and Huntington's disease. Inhibitory glutamate receptors (IGluRs) constitute a class of ion channel proteins equivalent to glycine and GABA receptors. Ibotenic acid acts on IGluRs (Cleland 1996)."

"AMPA, a synthetic analogue of ibotenic acid, displays the same typical moiety and was found to be more effective and specific glutamate agonist than the parent compound (Watkins, Krogsgaard-Larsen & Honore 1990)."

"There is evidence that damaged function of GABA mediated inhibitory synapses is implied in experimental and clinical seizure disorders. Decreased concentration, and then activity of GABA, may have a role in human epilepsy. Muscimol is a potent conformational analogue and biologically active bioisostere (Krogsgaard et. el. 2000)."

"This toxin tightly binds with the gamma-aminobutyrate receptor (de Feudis 1980). Moreover, it is also an inhibitor of neuronal and glial GABA uptake and a substrate for the GABA-metabolizing enzyme: GABA transaminase. Subsequently, some research teams tried to improve the potency of drugs. Lipophilicity is of considerable interest for the prediction of the transport, adsorption and distribution properties of molecules, and so is an important factor in drug design. More lipophilic bioisosteres of muscimol and GABA have been synthesized, such as Tiagabine. This drug was marketed as a therapeutic agent for the treatment of epilepsy, Gabatril ® (Krogsgaard-Larsen 1977, Krogsgaard-Larsen et. el. 1994, Krogsgaard-Larsen, Frolund & Frydenvang 2000)."

Here we have ibotenic acid and muscimol both having beneficial effects on human epilepsy and perhaps Huntington's disease or other neurological disorders. The reference to muscimol as a "toxin" is to be expected in a paper dealing with the chemistry of a "poisonous mushroom".

In the ancient world epilepsy was the proof that demons possessed certain humans, a belief that was only reinforced with every seizure, which can be very frightening to any onlooker, and devastating for the victim. Any substance that could cure or moderate this disease would have been held in the very highest regard in the ancient world. Most of the people in the New Testament, who are said to be possessed by demons with a detailed description of their symptoms; appear to be epileptics who are reported to be cured by the Christ/Eucharist.

I believe *Amanita muscaria*'s many medicinal benefits explain why Christianity first spread across the Roman Empire among the sick.

Testimonials

Patient Zero; Donald E. Teeter
Italic section originally published 2001 in The Sacred Secret

I purchased some dried *Amanita muscaria* specimens through mail order. On opening the bag, I was struck by a most pleasant aroma. Somewhere in my body an old switch clicked, it was as if my body somehow had prior knowledge of what was now in my hands. A small taste test confirmed that it tasted just like it smelled. It was not bitter or nasty at all, but sweet, actually tasty.

I ingested about 1/16 oz. weighed. The effects were very mild; slight euphoria; slight increase in ambient light, these pleasant effects lasted about 3 hours.

One week later, I ingested 1/8 oz. (3.5 grams.). More pronounced effects: general internal calm, very soothing; visual illusions of color, blue being especially brilliant; waviness of the visual field; slight impairment of walking; illuminated changing color patterns with eyes closed. After about 2 hours: drowsiness set in, lay down with closed eyes, extraordinary visual illusions, inner sense of peace. 4-1/2 hours after ingestion feel rested and back to normal.

One week later, 1/4 oz. ingested. Much more pronounced effects with quicker onset: a semi-dark room is brilliant with light, I walk like a drunk and lying down is mandatory. After about 2 hours: intense Persian carpet patterns with eyes closed, great sense of inner peace, some auditory effects.

One week after this, I ingested 1/2 oz. (about 3 specimens), very quick onset, just minutes. Laying down mandatory after about 1 to 1-1/2 hours: extreme inner calm; indescribable illuminated visions; extremely complex auditory effects, ranging from a narration of the visions to complex "sayings or teachings" for lack of a better word. The experience was not all one way as in being spoken to; to questions, it gave answers; sometimes the visions would illustrate answers! At some point, I spiritually journeyed to a place I can only call the kingdom of light. Everything seen was illuminated with an Inner Light. This vision was a cohesive whole, with a beginning, middle and end. The visual and auditory effects subsided after about 4-1/2 hours. 6 hours after ingestion, I felt rested and physically rejuvenated this sense of physical well being lasted for about 14 days after ingestion.

During the 1/8 oz. experience, I noticed a burning sensation at a cold sore site; I had been having cold sores (2 or so a year) since my early teens. The sensation felt just like a cold sore coming on. Some warts on my hand also tingled. The cold sore never did erupt. The warts tingled more with increasing doses, after the 1/2 oz. dose, the warts disappeared over night. It has been 10 years since I first tasted the Soma; I have not had a cold sore or a wart since!* Warts and cold sores are two different kinds of Herpes virus. This mushroom appears to me to be an antiviral agent.

> *It has now been 14 years that I have been without a cold sore or wart; several Physicians and other health care workers have told me that modern medicine can only suppress the symptoms of cold sore herpes; that there is no known cure, and that complete remission from the cold sore herpes symptoms for more than a decade is very unusual.

Reasons why I believe *Amanita muscaria* contains one or more antibiotic, antiviral agents.

1. Ancient references to healing, spanning 2000 years.
2. Presence of the herb in milk can retard its spoilage for over 24 hours at a room temperature of 60-65 deg. F.
3. The penicillin like property of being excreted (urinated) unchanged a very useful property for an antibiotic.
4. The urine containing the drug also shows a delayed spoilage.
5. The mycorhiza fungus, as a symbiot with trees, is reported to manufacture antibiotics for its host tree. Such chemicals may be just as useful in fighting infection in a mammal as in a tree.
6. The personal experience of being healed, and the observation of other people being healed by *Amanita muscaria*.

In the spring of 2002 I was in Austin Texas; and one morning I woke up with a burning pain deep in my left hip and it was very hard to walk. Over the next few weeks the burning pain spread across my lower back and into my right hip, walking was now very painful. Approximately a month after the first symptoms appearance I was diagnosed as having Arthritis, the pain was excruciating and I couldn't walk more than a few steps without a cane. I did not have any *Amanita muscaria* mushrooms, the preceding summer in upstate New York had been very dry and I didn't find very many and those few were now gone.

Then I met David at the Gardens of the Ancients; in Manor Texas, he was very interested in the *Amanita muscaria* mushrooms and he ordered a pound from a supplier. About ten days later they arrived, and David invited me over to show him how I used the mushrooms. I made up some Ambrosia; a simple cold-water extract, and that evening we consumed some small pieces of mushroom cap washed down with the Ambrosia.

The very next morning the burning pain was greatly reduced and I had much better mobility. A few days later I purchased a 1/4 oz. and consumed them all. The next morning the burning pain was completely gone from my back and both hips and I could now walk upright without the aid of the cane.

I no longer get colds or flu's; at the first sign of a cold or flue I simply consume a small piece of mushroom (1-2 grams) and all symptoms disappear; usually within a few hours. One time I was away from home visiting relatives, and I came down with a nasty flue that was going around; I had no A. M. mushrooms with me, and I got very sick, very quick. On returning home the next day I consumed about 1/8 oz. of caps and stems and went to bed, about 8 hrs later I woke up feeling well, with no symptoms of this flue.

A small piece of *Amanita muscaria* mushroom cap placed on an infected tooth and left on for several hours will kill off the infection very quickly; the pain usually stopping in less than an hour; with the infection usually cured with one or two small pieces of cap.

I watched my son Neil cure Kennel cough (a communicable canine lung infection) in three dogs with a small bowl of ambrosia given to each one; which they quickly consumed, with complete remission of all symptoms from just one dose. Several people have told me that Kennel cough can be very hard to treat with the standard antibiotics and often takes months. The fact the dogs consumed the ambrosia so readily; shows me that they instinctively knew it would be good for them.

I have been suffering from chronic back, hip, and leg pain for about four years. Recently, I was told by an Orthopedic Surgeon, that I had Bursitis in my hip and Tendonitis in my back. I could hardly walk and I shuffled about like the elderly, the pain was exhausting.

I was encouraged to try the *Amanita muscaria*. The first day I sucked on a cap for a while and then ate it. That evening I made a tea with it. The next morning, I had regained the mobility in my hip; I could now take normal strides. I continued to take the mushroom in some form twice every day for two weeks.

I still suffer some pain, but I can walk much better now.

Twice I have used the mushroom for dental care. Once after a lot of dental work my gums were sore, recently for a gum infection. I put a piece of cap over the affected area like a Band-Aid and sucked on it. Both times it pulled the infection out. 6/8/04

I consume small quantities of dried *Amanita muscaria* mushroom as needed whenever I feel sad or anxious. I never felt "high" on *Amanita muscaria*, just what I considered normal, I still feel my emotions but with *Amanita muscaria* I don't feel controlled by them.

While using this Mushroom I have noticed my ever-present insomnia is gone and I sleep better than I have for years. I have also noticed Colds and Flues are now so mild I don't take medication to control the symptoms. However, I do eat more dried *Amanita muscaria* mushrooms when I start to feel sick.

One small dose of 1 to 2 grams of dried *Amanita muscaria* mushroom at night is all I need to take for maintenance; I sleep very well and don't have as many body aches or pains. Over the years I have used prescription as well as illegal drugs to treat my insomnia and to escape from emotions I didn't want to feel. Often the side effects and increasing tolerance of these drugs brought on a deepening dependency and depression, as these medications would leave me either intoxicated or sleepy.

Now with *Amanita muscaria* it's nice to be both sober and in control of my body and mind. 5/5/05

We have noted repeatedly that *Amanita muscaria* has a number of healing properties; these include arthritis and joint pain relief, stomachaches or nausea, diarrhea, toothaches, anxiety relief, insomnia, and a reduction in generalized infections. In all of these cases we have seen a clear repeatable pattern of *Amanita muscaria* helping in the above ailments.

Arthritis and Joint Pain
I have noticed a number of people that had near miraculous improvement in hip and knee pains after taking doses of *Amanita muscaria*. Researchers have noted in the last 5 years that the most prevalent forms of arthritis are caused by a nanobacteria. During the active period of the experience pain seems to vanish and the body feels almost pain free, I have noticed this dramatic effect myself and many other people have also commented on this feeling. I am sure this is partly due to the mental effect of the muscimol, but I also suspect there is an antibacterial and antiviral and antifungal effect of the *Amanita muscaria*. This reduction in the activity of these internal populations of nanobacteria could also account for the significant reduction in pain due to ingesting the mushroom or its other products.

Nano bacteria and the Heart
In scientific papers we have studied we have noticed that *Amanita muscaria* is clearly antibiotic and antifungal. But the ability of *Amanita muscaria* to kill or reduce the populations of nanobacteria is remarkable. The effect is not permanent but does seem to be additive over time. Nanobacteria also play a major role in heart attacks, tooth and gum disease, and cardiovascular disease particularly the build up of plaque.

Although we have not directly studied the effect on the heart and cardiovascular, I would suspect that the de-stressful aspects of *Amanita muscaria* and the ability to control nanobacteria might make it a very powerful heart medicine. Other mushrooms are renowned heart medicines such as Reishi, shitake, cordyceps and other mushrooms. I would not be at all surprised if the ability of these species to kill nanobacteria is the principle benefit to the heart and cardiovascular.

Toothaches
We have noted a clear improvement to toothache pain and infection by placing a piece of *Amanita muscaria* over the painful tooth or gum area. Although the effect is not as potent as peyote the effect is noticeable and repeatable. *Amanita muscaria* relieves the pain, inflammation and swelling of the tissues and also is good at de-stressing the subject since tooth pain is very stressful and agonizing.

Anti-anxiety Agent
Amanita muscaria is a remarkable de-stressing agent, during the active period of the dosing the *Amanita muscaria* is very calming to the nerves and most people who are stressed out will quickly find themselves in dreamland. The effect is so remarkable that many paintings of the middle ages show people who have eaten *Amanita muscaria* passed out in the fields along a brook or in the forest. One of the most obvious and sure properties of *Amanita muscaria* is the effect that a tired worn out person will soon find himself in deep sleep if they take a dosage in excess of 7 to 10 grams. Other effects include a stabilizing of the nerves and the nervous system as the nervous systems seems to get a break and calm down, allowing the subject to get needed rest that their anxiety condition has prevented. *Amanita muscaria* is really a god send when an over stressed person needs to break the cycle of stress that seems bound to be a downward spiral into insomnia and anxiety. Usually the day after the dosage the subject feels good, unlike alcohol, which stresses the nervous system and makes you feel hung over. The *Amanita muscaria* makes one feel refreshed, revitalized and relaxed.

I sincerely hope that anyone considering gathering this mushroom will buy a good field guide. I have looked at many; the best field guide I have found to date is the Audubon Society Field Guide to North American Mushrooms; the real photos are a great help. There are several other species of mushroom that may confuse an amateur, some have unknown toxicity, some are edible but they are not the herb of Life. A good field guide will help in determining exactly what you are looking at.

All mushroom literature will state that *Amanita muscaria* is poisonous! Fresh mushrooms are somewhat toxic, proper drying, however, radically changes the mushroom's chemistry. Some literature also lists this plant as a hallucinogen, without mentioning the fact that it has to be dried to be psychoactive, that's irresponsible, being an advertisement to misadventure. Other literature mentions the Siberian use as a hallucinogen, and then maintains that the Siberian *Amanita muscaria* is different from the North American *Amanita muscaria*. This is not the difference, drying is the difference! The Siberians thoroughly dry theirs before consumption, while Westerners are making themselves sick on raw ones!

The spores of this Fungus are small enough to ride the wind to anywhere on the planet! Siberian spores are landing in North America while North American spores are landing in Siberia.

There may be local variations in areas but this species is breeding planet wide and some of the variation may just be differences in growing conditions: New York to New England and coastal California being home to a golden yellow variety with the occasional orange or bright red one appearing; the west coast range and Rocky mountains produce a blood red variety with the occasional orange or yellow showing up, orange is found over most of the remaining country with the occasional yellow or red ones. From yellow to orange to red, they all seem to have the same effect and identical taste, if dried identically. In comparing independent chemical analysis of *Amanita muscaria* specimens from Italy, Holland, South Africa, Japan, North America and Siberia no significant differences were found in this fungi's chemistry.

It is interesting to note that the red, orange, and yellow specimens are sometimes indistinguishable from each other when dried, turning to a dull gold color on the cap. Some literature states that there are several different color varieties of *Amanita muscaria*, each having its own variety name: as in *A. muscaria* var. *muscaria*, red fly Agaric; *A. muscaria* var. *formosa*, the yellow orange fly Agaric. The Fly Agaric even has a white variety. The experts are not done thrashing all this out yet. I, however, only gather the yellow, orange, or red ones.

Host trees seem to make a slight difference in potency; in my personal experience the ones growing with any species of pine being slightly better than other host tree species. In your area it may be a different tree host that yields the best herb of Life. The *Amanita muscaria* is a mycorhiza fungus and it lives in a symbiotic relationship with certain tree species. The body of the fungus actually coats the tree's roots. It supplies the tree with water, nutrients and antibiotics; in return the fungus receives food.

Living *Amanita muscaria* is often found with paralyzed insects and slugs that tried to eat the mushroom. If you remove the comatose victim it regains its senses in about 20 minutes. The fungus sheathing of tree roots probably protects against insect and nematode attack. The fungus could, in fact, be a predator of small life forms, paralyzing its victims and then absorbing them, this small prey being a ready source of nitrogen and other nutrients needed by the fungus and its host tree.

The common name Fly Agaric is based on the folk belief that it kills flies. I have not found that to be true; they simply become comatose if they are exposed to fresh fly Agaric. Dried fly Agaric in milk is very attractive to flies; they are irresistibly drawn to it, becoming hilariously intoxicated after consuming it. The flies recover in 12 to 24 hours, seemingly none the worse for the experience.

10. Natural Science; Pharmacology

Living *Amanita muscaria* contains mainly Ibotenic acid; a trace of Muscimol may be present on the outer surface of the mushroom. Extremely small trace amounts of approximately 15 other chemicals are also present. Fresh *Amanita muscaria* should never be consumed! While not deadly poisonous they do not have the desired properties; all references to human poisoning are from fresh Fly Agaric. To be used as the Sacramental Herb of Life; the *Amanita muscaria* mushrooms must be thoroughly dried!

All species of mushrooms when fresh including *Amanita muscaria* contain a form of hydrazine that has been used by NASA as a rocket fuel; the amount of this hydrazine varies widely from species to species, and widely among individual mushrooms of the same species. No one has figured out why all mushrooms make this hydrazine since mushrooms would seem to have little need for rocket fuel. This hydrazine is not good for you when it's consumed; drying *Amanita muscaria* completely dry and then aging them for a few months will remove this hydrazine.

In drying *Amanita muscaria*, the Ibotenic acid is converted to Muscimol. Muscimol is present in the dried specimen in very small amounts, approximately one milligram per gram (1000 milligrams). Trace amounts of unconverted Ibotenic Acid are also present. Drying the herb in the sun produces a trace of a variant of Ibotenic Acid called Muscazone; this is far less potent than Muscimol with different effects.

The herb's effects are from a combination of these chemicals; the varying proportions of these chemicals lead to variation between individual plants. In actual practice, this variation is not of great concern; some individual plants may be stronger or weaker, the practice of averaging a batch from many specimens tends to produce an average.

Processing also has an effect on chemical makeup. Shaded cool drying producing more Muscimol than sun drying. Heated drying's effects varies with temperature and above 130 deg. F the mushroom cooks and the heat actually starts breaking down these chemicals. Room temperature to about 120 deg. F seems to be the best in my experience. I do not sun dry but you may choose to. If you have a regular food dehydrator with an adjustable temperature control, use it. As long your drying practices are consistent from one mushroom to another, the result seems fairly constant.

Scientific studies of the effects of isolated pure samples do not apply to the mushroom. They are, however, very useful in determining the effect of each chemical.

Ibotenic Acid's effect on the eyes is dilation of the pupil. The only mental effect seems to be sedation. This probably accounts for the coma like sleep and stupor reported from fresh *Amanita muscaria* ingestion. On drying, Ibotenic Acid loses CO_2 and becomes Muscimol.

Muscimol is the prime chemical for the dried herb's action. Muscimol dilates the pupil; and is the main component causing mental effects. Muscimol is relatively stable as a chemical; both it and Ibotenic Acid are very water-soluble. Muscimol is 4 to 10 times as active as Ibotenic Acid. Muscimol is a very polar molecule, with a strong - and + charge on opposite ends of the molecule. The effects of pure Muscimol are reputed to be similar to dried *Amanita muscaria*.

Ibotenic Acid if exposed to ultraviolet light produces Muscazone. Muscazone has less potency than Muscimol, but more than Ibotenic Acid does. It is present only in trace amounts in the herb.

There is no practical reason to try and isolate or concentrate these chemicals. Nature has produced an ideal mix already and the natural potency is just about right for practical use. Any water extract made from the herb for consumption (i.e. Ambrosia) will be weaker still. Because of the dried herb's low potency (1 mg Muscimol per 1 gram herb), accidental overdose would be almost impossible. Overdosing by misadventure is a different story. All doses should be weighed, with a maximum 14 gram = 1/2 oz = about 3 specimens, as the upper most limit per 200 lb. person. Smaller people should, of course, use less (1/8 oz per 50 lbs. body weight max). Remember that all medicinal herbs should be kept out of the reach of children!

The most pleasurable range for most people is from 3.5 gram = 1/8 oz to 10 gr. = 3/8 oz, this would be equal to 3 to 10 mg muscimol. People familiar with dried *Amanita muscaria* can detect faint effects from less than 1/2 gram.

Some Herbal Principles

The effect of a drug plant is subject to a few variables. First, the absorption rate of the active principles into the body, second, is the physical size of the pieces of plant that are releasing the active principle.

This second variable is subject to manipulation. As an example, if you eat a given weight of dried *Amanita muscaria* in one piece, say a 1/16 oz cap rolled up and swallowed whole, the experience will be lighter and longer lasting, than the exact same piece reduced to a fine powder before being eaten where the active principle is released faster from the smaller pieces, absorbed faster and excreted faster, leading to a more intense effect over a shorter duration.

Another variable encountered with any herb plant is the variation in potency between individuals of the same species. This variability is beyond human control. We can, however, reduce this effect, if we use pieces from a number of specimens in our preparation we end up with an average of the total. This average will be more predictable in effect than individual specimens since extra strong or weak individual herbs are averaged out by this method, a sample of the batch being representative of the whole batch.

Lastly, is preserve ability; all herbs decline in potency over time. Such things as oxygen, moisture, light and heat all work to change any herb's chemistry. Physical changes may accelerate these changes; grinding an herb into a powder, for example, allows herb chemicals to escape and other things, like oxygen, in.

The herb of Life is no exception to this rule. The *Amanita muscaria* must be dried before use! The large pieces resulting from this drying, if stored in sealed plastic bags that are then placed in airtight plastic or glass containers preserve fairly well. The herb degrades rapidly if over exposed to the environment or is powdered or otherwise altered from its storable form. It is best to only prepare as much herb of Life as will be immediately used.

11. Natural Magic

The following material details how to find and prepare *Amanita muscaria* for use as a sacrament.

It is up to the reader to exercise caution and restraint when first trying the *Amanita muscaria* mushroom; individuals vary widely in their response to various substances. It is much better to have a lighter pleasant effect than to be overpowered. While I personally have never seen anyone experience a bad effect, there is always that possibility.

Our ancient fathers called it the herb of Life; let's keep it that way. The *Amanita muscaria* is Sacred; treat it and yourself with respect. To find and consume the *Amanita muscaria* mushroom is to embark on a spiritual quest.

This knowledge is given so you may have the power of choice. If you wish to use the herb for healing, you can, if you wish to explore the Sacred, its here. The herb of Life is your birthright! No man, or assembly of men, has the right to deny you contact with the divine.

The Hunt

Finding the herb of Life is a sacred hunt, the *Amanita muscaria* mushroom, as mentioned in Natural Science, is a Mycorhiza mushroom. It lives in a symbiotic relationship with various species of trees such as Pine, Spruce, Larch, Birch, Beech, Maple, Hemlock, Fir, Hazel, Olive, and occasionally, the Oaks. So, I don't hunt the herb as much as the trees that support it. The *Amanita muscaria* mushrooms will always be found in association with these trees, in the area encompassed by the tree roots. The herb also needs drainage; sandy soil or sloping terrain seems to be preferred.

Over most of North America the fungus fruits from June to November. In California and Florida it fruits in some areas in the winter, the only sure way to discover where the herb is to spend as much time on the hunting as you can afford during its season.

Once you have found the *Amanita muscaria* mushrooms in a certain place, returning there to check from season to season is usually a good idea. Eventually you will compile a list of areas where you know the herb lives. It then becomes a matter of catching the fruiting. Do not be greedy, this plant is essential to the life of the forest; I always leave the older worm eaten and the very young buttons. The old ones don't taste good but are still releasing spores while the very young buttons could easily be confused with a button of a different fungus. If all you find are young buttons; try to return in a day or two; they should be in their prime by then.

A prime specimen has a basically flat cap and is about its full size. It should be fresh looking and undamaged by insects, slugs or weathering. Rounded caps mean it is 1 to 3 days from maturity. Upturned edges on a cap mean it's an older specimen; as long as they look fresh all three levels of maturity can be harvested.

A few simple items make harvesting easier. A basket to carry them in, lined with a clean cloth, a couple of small clean soft brushes to remove debris from the specimens and a flat blade screwdriver or an old stiff kitchen knife. Just slide the screwdriver or knife into the ground next to the specimen's stem and pry up, it should just pop up whole.

It is a lot easier removing dirt and debris from the specimen before it starts to dry and the less dirt in the specimen basket the better, so I try to clean them thoroughly as I am harvesting with brushes and my fingers. Removing the stem from the cap at this time seems to result in less over all damage, as does segregating the caps from the stems in the basket since the caps are somewhat fragile.

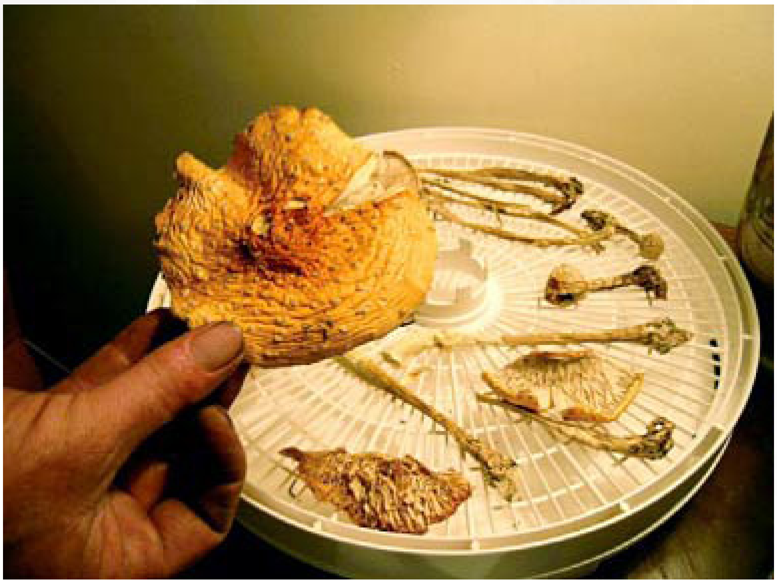
Amanita muscaria should be dried as soon as possible after harvest. Final cleaning of the herb should be done before drying. Sometimes a thin layer of soil is actually trapped in the skin of the stem's butt. Gently scraping with a knife will remove it; a final cleaning can be done in this area after drying.

A basket of *Amanita muscaria* mushrooms.

Preparing the Plant of Life

Once fresh specimens are obtained they must be dried before use! I remove the cap from the stem (if not already done) and slice the stem into quarters lengthwise the cap will dry whole. Placed on a screen or rack with good air movement they should dry in a day or two. If placed over a heating vent or oven dried, do not exceed 120 deg. F. A conventional food dehydrator with a temperature control works very well. Dry the *Amanita muscaria* mushrooms until completely dry; it should be cracker dry, pieces should snap when bent. Once dry it should be placed in sealable plastic bags, sealing the dried herb of Life in the bags creates the most delectable fragrance, it's no wonder the ancient Aryans also called it "Andhas" R.V. literally "the flower." These bags can then be stored in glass or plastic containers; store in a dry cool dark area.

These dried *Amanita muscaria* mushrooms should be aged for 2 or 3 months before using to allow a good curing of the specimens. Proper drying and curing is essential for both good taste and potency. The bread of Heaven can be simply eaten as is or used in the following preparations.



Dried *Amanita muscaria* pieces being removed from the drier.

WARNING: Do not consume any carbonated beverage, (beer, soda, etc.) before or after consuming the dried *Amanita muscaria*. It appears that Muscimol can be reconverted into Ibotenic Acid in the presence of carbonated water. This reverses the effects of drying where Ibotenic Acid loses CO_2 and becomes Muscimol. The resulting effect being similar to fresh *Amanita muscaria* ingestion nausea, vomiting, stomach cramps, stupor, coma like sleep, excess salivation and no hallucinogenic effect!

Magic Food

In Soma: Divine mushroom of Immortality it is mentioned that the Siberian tribes using *Amanita muscaria* often placed the dried mushroom into soups and stews thus creating magic food and this is one of the most enjoyable ways of consuming *Amanita muscaria*. Crushed or powdered dried *Amanita* can easily be added to a bowl of stew, soup or oatmeal and actually makes the food taste better. This is probably the best way to begin using the Herb of Life.

Ambrosia; elixir of Life

It's easy to turn water to wine if you have the properly dried specimens. Simply weigh out the desired amount of dried *Amanita muscaria* pieces. Place cap pieces upside down in the bottom of a small Mason type jar. Break stem pieces into 1/2" to 1" lengths and place on cap pieces. Shake gently to settle pieces into the smallest volume. Add just enough cool drinking water to cover the herb and let soak for at least 3 hours at room temperature. The water should be a dark amber color.

Pour off the ambrosia into a second glass or jar (using a strainer), cover the second jar and set aside. Add the same amount of new drinking water to the *Amanita muscaria* pieces in the first jar, let sit for at least 2 hours. This water should become almost as colored as the first run. Strain liquid as before, into the second jar, which already holds the first run. A third run may be taken if you wish but it will be considerably weaker than the first two extractions. I usually press the pieces with a fork to squeeze out more ambrosia, and then rinse the pieces and the first jar with a small amount of water, strain and add to the second jar.

This procedure yields ambrosia that is both tasty and potent. The original pieces being left somewhat larger for a reason, the mushroom is in fact a pump. When rehydrated with water it goes back to pumping water through its body, leading to a fairly efficient water extraction of the water-soluble chemicals.

It takes slightly more dried *Amanita muscaria* per dose, when making ambrosia than just consuming the dried mushroom, but the resulting experience seems clearer and cleaner with the ambrosia, with only the most water-soluble chemicals and sugars being in the ambrosia. This concentrated ambrosia is sweet to the taste. The flavor of well-made ambrosia is unique, tasting to me like a weak honey, malt and water solution. Just like coffee, tea or beer making, the quality of the water used has an effect on the taste. Reverse osmosis or distilled water yielding the best flavor.

The similarity between the word ambrosia and amber, probably relate to the color of the ambrosia, which is always a shade of amber. Ambrosia being yellow amber in transmitted light and reddish amber in reflected light.

The ambrosia is best when sipped slowly and allowed to lie on your tongue for a few seconds before swallowing.

Sacred Wine

A variation of the standard Ambrosia is to substitute Grape juice for the water. You can make this Sacred wine very easily by using approximately one oz. (28 grams) of dried *Amanita muscaria* per quart of grape juice, soak for 8 - 12 hrs then strain off the juice and press the mushroom pieces to recover more juice, which is added back to the strained juice. It seems to me that a slightly acidic Grape juice works best and a few drops of vinegar added per cup of juice at the start seems to make it more potent.

This wine has the unique property of getting more potent (up to a point) from being diluted with water! For best results you should dilute this wine using 2 - 4 cups water for every cup of wine before drinking. When properly diluted with water it will slack your thirst, if it is not diluted enough it will dry your mouth in a few minutes.

Preparing the Seer's Milk

The mixing of milk with the herb or the expressed juice is a very ancient practice dating back at least 4000 years; and, reports from Siberia dating from the 1900s report the fermenting of dried *Amanita muscaria* with reindeer milk. In the Rig Veda, the expressed juice is mixed with soured milk and curds before being consumed, no time seems to have been allowed for fermentation. The lactic acid present in the soured milk probably reacts quickly with the Muscimol, converting it to a more potent form.

Personally, I can't drink sour milk so I use a different method. I place small pieces of the herb into a bowl or jar and add whole homogenized fresh milk: 3/4 - 1-cup milk per one average sized (5-7 grams) shredded dried specimen. Place in a cool room (60-70 deg. F.); cover the bowl with a clean cloth or paper towel.

If there are any flies in the room, they will show you when it's ready, they will be drawn to it like iron to a magnet. If a drop is placed on a plate, when the flies find it they will become intoxicated. Just the smell of it seems both irresistible and intoxicating to them. This property explains the ancient Biblical name Beelzebub the Lord of the Flies.

If there are no flies around, pull a drop out every hour (with an eyedropper) and taste. At 60 deg. F. it may take 12 hours or more to ferment. The milk will not readily spoil and still tastes sweet after 24 hours. At about 30 hours it turns to a non-psychoactive yogurt that then spoils. The fact the milk doesn't readily spoil shows the antibiotic properties of *Amanita muscaria*.

Properly fermented milk is much stronger than the herb or ambrosia. You will know when it is ready with the one-drop taste test. When you are sure it's reached its peak, strain the milk into a glass or cup. Press the pieces in the bowl with a spoon or fork to try and recover as much milk as you can; sip very slowly and enjoy.

Preparing the Holy Oil

Olive oil and animal fat are both absorbed into the skin. As far as preservability goes, olive oil has an edge over animal fat, especially in warm or hot conditions. The active principal of the herb can also be absorbed into the skin; if you gently hold a fresh *Amanita muscaria* stem in your hand for about 5 minutes, you will start feeling a light giddiness, the longer the contact, the more intense the effects.

To create the holy oil, powder some dried specimens and sift the powder through a fine cloth. Return the pieces that didn't pass to being re-powdered. Once you have the desired amount of fine herb powder, place into a clean dry small sealable vial or bottle. Slowly add just enough olive oil to cover the powder. Using a piece of wire, gently stir the powder and olive oil together. Add more oil as needed to create a thin paste. Seal the container and let the herb soak in the oil for an hour or two. To use, place a fingertip on the surface of the oil and apply to the center of the forehead about an inch or so above the eyebrows. The effects should start in a few minutes and last until the oil is all absorbed. This is the most controllable method of using dried *Amanita muscaria* and probably the most efficient way of using a limited quantity of dried mushroom for a number of people. The effects are never too intense unless too much oil was applied.

This oil is also a very effective topical antibiotic and can be used on many different infections of the skin; such as inflamed insect bites or other infected wounds.

Preparing the Living Water

If you eat the dried herb of Life, drink the ambrosia or consume the milk of prophecy, you will produce the Living Water. The dosage going in determines the strength of what comes out. Approximately 7/8 of the active principal is excreted in the urine. The rest is probably sweated out. Recycling the active principal is a way to greatly extend the duration of the experience with a given amount of herb.

Many people will be disgusted at the thought of drinking their own urine. Fresh urine is, however, more sterile than tap water if you do not have a kidney infection. Urine spoils very quickly when exposed to microbes from the air; they multiply rapidly in the nutrient rich solution. The presence of the herb's essence in the urine does slow down such spoilage, another sign of antibiotic action. Personally, I have never tasted the Living Water; you are on your own with this one.

Preparing the Eucharist

The modern sacrament used by the older Christian churches is obviously descended from something; the water is now reputed to be composed of wheat flour. But what was it originally? If you believe the herb of Life is the Christ, then the herb as the Bread of Life would be the source of the sacramental flour.

Amanita muscaria, when crispy dry, powders or grates easily. A mortar and pestle works well today just as it would have anciently, it's just slow, and a small coffee grinder easily disintegrates it. Herb flour is made by sifting the ground powder through a fine cloth or screen to remove the larger pieces. These larger pieces are then reground and re-sifted. This is exactly the same technique used in the production of fine grade cereal flour. Eventually, you get most of the dried mushroom to sift through as herb flour. Gram for gram, herb flour is the strongest preparation that is easy to make.

This flour has many advantages for sharing among a number of people. First, the averaging effect of using multiple plants, second, in setting an accurate dose for each water from a batch of flour. When pressed into waters it is easy to handle; placed on the tongue, the water dissolves quickly and is totally absorbed, the water also dissolves easily in wine, grape juice or water.

Creating the waters is more involved than some of the other processes and will require the construction of some simple equipment. You will need a sifter and a press. The best sifter is created with two wide mouth Mason type jar ring lids. Place top-to-top, line up and tape around the outside of both with duct tape. You now have a top with two threaded ends on it and a hole in the middle. A piece of fine cloth is placed over a Mason type jar containing the course herb powder. The double lid is screwed down over the cloth onto the jar. A clean, dry, empty jar is now screwed onto the other side of the top. To sift, you place "course powder" jar up and shake. The fine powder will collect in the empty jar that is now on the bottom. The advantage of this sifter is that you don't lose much fine dust.

The cloth should be sheer and fine in weave. The threads should be smooth, not fuzzy. The ideal fabric looks like a fine screen when held up to the light. The cloth must be perfectly dry or it won't sift.

The ancient style of sifter can be easily recreated with an embroidery hoop and a piece of cloth. Sift into a large shallow bowl. A gentle motion is all that's needed. The advantage of this sifter is that it can be much larger in the cloth area than a wide mouth jar lid. It sifts faster but must be used in a draft free area, and you are going to lose some fine dust.

For the herb flour to be turned into a water, you need a press. In the Sacred Secret I gave instructions on how to build a simple but crude press. Then I discovered that presses could be purchased from Church supply houses that are specifically made to produce the Eucharist water; these presses can do a superior job than the home built one.

It may take some experience and trial and error to tune the operation. The waters should be pressed hard enough to withstand some handling and still dissolve on the tongue or in liquid.

Using a set of measuring spoons, determine the amount of herb flour to be used for each water. Then, use the spoon chosen to set the volume for every water produced from that particular batch of flour. This achieves uniformity from water to water, especially if the spoon is over filled and then struck off level with a knife.

When not being used, the die pieces should be stored in a clean dry area. Anything that touches the herb flour should be dry!

As you can see, the technology needed to create the water type herb sacrament was easily in reach of the early Christians. Everything involved was already in use in ancient Middle Eastern herbal practices. The early Christians had good pharmacological reasons for developing and using the herb flour water as a sacrament. The use of this technique stretches the supplies of the herb to its maximum by obtaining maximum effect from minimal amounts. There are other reasons why this form of sacrament was adopted. One, people who would never eat a toadstool would have no problem eating it as a water. By concealing the true identity of the sacrament from both followers and enemies, the priesthood maintained control and power over the one and denied their enemies information. The sacrament could easily be substituted with cereal flour if the supplies of the herb ran out, or, if they thought the authorities were going to raid.

Like all other herb of Life preparations, grind no more flour than will be immediately used.

Honey Drops

Once you have mastered the technique of producing herb flour, you may wish to make honey drops instead of waters. There is no need for a press. Simply produce the desired weight of flour, and then slowly and carefully fold in a small amount of pure honey. Work into a thick putty consistency. Roll into ball's 3/4" to 1" diameter or flatten out into a water.

The addition of honey makes a very tasty candy. The honey also seems to improve the absorption of the herb's essence. Like all other herb of Life preparations, it should be made and used immediately.

Set and setting

When *Amanita muscaria* is used Sacramentally, the set and setting are very important. The experience evoked by any psychoactive drug is affected by the set and setting where the drug is taken. The set means the individual's expectations of the coming experience, the setting, is the physical environment where the experience is taking place.

This herb will probably not be popular as a party drug. The increased sensitivity to light and sound can be too much for a party scene. Daylight use is probably not a good idea either as a sunny day can actually be painful. Some of the shamans of Siberia, who use the herb, practice their magic in complete darkness. Early Christians also seemed to favor dark rooms or areas, catacombs, etc. (See Matthew 10:27). The auditory effects are best heard in a quiet environment; and of course, distractions should be kept to a minimum.

No one should consume more than 3.5 gr. (1/8 oz.) of the herb of Life while alone. Higher doses may produce a disassociate effect, leading to a short-lived but complete break with reality. Many people will also lose their equilibrium and stagger and fall. Both of these effects may result in physical damage from falling or other accidents. There should always be a watcher (an unintoxicated person) to guard against these events. And, of course, only an idiot would drive a vehicle while under the influence of the herb of Life!

Do not mix the dried *Amanita muscaria* with other Drugs, Prescription, over the counter, or illegal.

WARNING: Do not consume any carbonated beverage (beer, soda, etc) before or after consuming the dried herb of Life. It appears that Muscimol can be reconverted into Ibotenic Acid in the presence of carbonated water. This reverses the effects of drying where Ibotenic Acid loses CO_2 and becomes Muscimol. The resulting effect being similar to fresh *Amanita muscaria* ingestion, with nausea, vomiting, stomach cramps, stupor, coma like sleep, excess salivation and little or no hallucinogenic effect.

12. The Resurrection Question

It occurred to me late in the construction of this book (The Sacred Secret) that I had not addressed a fundamental belief of Christianity, i.e. the idea of the resurrection of the Christ.

In order for my theory to hold up, the herb of Life (*Amanita muscaria*) must be able to resurrect. At first, I believed the ability of the dried specimen to absorb water, rehydrate and continue to release spores; an ability mycologist refer to as resurrection was the answer. But this rehydration would happen before the plant was ritually killed (pressed and extracted). A true resurrection of the plant would have to happen after it had been so killed.

After re-reading the New Testament statements, the idea that I was reading a recipe or formula encoded in myth took hold. The constant reference to three days seemed to be an essential part of the formula. Since the rehydration with water can take place in minutes to hours, it again did not fit the three-day references.

Returning to the Rig-Veda, for more information, I discovered that the water used for rehydration had grain (barley) boiled in it, before being used on the Somas. This would result in a very nutritious food source for the fungus. A puzzling statement was also found, referring to "these ancient Somas and these new ones." The new Somas were obviously ones picked and dried. But what could these ancient Somas be?

In Wasson's Soma, the Siberian tribes, using *Amanita muscaria* as an intoxicant, preferred older specimens that had dried in the ground; a fuzzy feel to the stem and a dark color distinguished these mushrooms. During the summer of 2000, while gathering specimens, I came upon several old specimens that had turned black. Each one was covered in a silvery gray long hairy mycelium; some of these hairy strands were more than 6 inches long. Closer inspection of these older black specimens with a hand lens revealed that the fuzz was erupting from the body of the mushroom and growing back into the ground; everywhere this fuzz touched the forest floor it had eaten the needles and leaf litter creating a bird nest like depression in the forest floor. Now was this fuzz the actual *Amanita muscaria* plant; after all, the specimen is just the fruiting body? I had seen this hairy mold many times before; it appeared on specimens that had been water extracted then left in the jar for a couple of days. Had I, in fact, been resurrecting the herb of Life without knowing it?

Like everything else dealing directly with the herb of Life in this book, it was time to experiment; time to see if the *Amanita muscaria* lived up to its ancient name Ambrose "not mortal."

Dried specimens were extracted with grape juice, barley water or honey water. In all cases, the pieces left after the extraction, erupted in silvery, bluish Grey mycelium within three days at a normal room temperature. These were allowed to grow for up to three weeks after extraction. They were then dried and re-extracted. In all cases, the liquid extract was again psychoactive. This cycle was repeated three times with no real change in psychoactivity; it appears that, as long as the herb of Life is adequately fed, the cycle can be repeated indefinitely!

One must ask oneself, how could this plant get a reputation and several names based on it being immortal unless the ancients knew of it's resurrect ability? How else can this extremely ancient belief be explained? (Ambrose = Not Mortal, NekTar = Death Overcomer, Born Immortal, etc, etc.)

Always in this study, I have tried to maintain scientific and common sense principals in this search for knowledge. It should come as no surprise then, that scientific study could recover a lost science, and this is exactly what we are dealing with here. It is an ancient science of spirituality, not religion as we moderns conceive of religion.

The New Testament is ancient scientific (empirical) knowledge embedded in a story. Some ancient people were keen observers, even if their observations are explained in words and concepts foreign to our thinking. This in no way invalidates their observations or their conclusions.

There are only two ways to preserve complex knowledge without writing, both methods known to students cramming for a test.

First, make it poetry or song where the rhyme helps remember the information, the Rig Veda is a prime example of this, where the poetry of the Hymns lends itself to being used as such a vehicle of knowledge.

Second, make it part of a story. In remembering the story, the knowledge is remembered, but the story itself must be memorable. The New Testament is an example of this second method. As long as you know this story actually contains hidden knowledge, there is no misunderstanding; but if you don't know it is really a vehicle for transmitting hidden knowledge; and so believe it to be literal, then misunderstanding is all this method can produce.

All the major points in the New Testament such as "the virgin birth," "water to wine", "healing," "prophecy" and "the resurrection" fit *Amanita muscaria* precisely. They do not fit a man or any other life form on the planet.

The rediscovery of this plant's resurrect ability is the last piece of the puzzle. It is the last major point in this Mushroom's identification as the Christ in the gospels of the New Testament. This mushroom resurrects so simply and naturally, any aware human, liquid extracting the mushrooms rather than just eating it could discover it quite easily.

Could any plant be more magical in the eyes of ancient people? Consuming an extract of a hallucinogenic plant, that will not die, would be the ultimate act of magic for the ancients. Nothing else could even come close to the power of this act. The fact that this Fungus exhibits antibiotic action would only reinforce this belief, all the more so if it actually extends a human's life span!

We have now come to the very foundation of religious belief in the west, this being human immortality. "We have drunk the Soma, we have become immortal" claim the Seers in the Rig Veda. Of course, they have become immortal, for they have drunk the immortal Soma. Can the New Testament's claims of consuming the Christ and immortality be understood any other way? No, it can only make sense in this context, that if you consume the immortal, you become immortal. This is pure magical thinking, exactly the kind of thinking you would expect to find at the very dawn of religion.

All religions are descended from shamanism; and a shaman's job is to make contact with the divine; could there be any more divine life form available to make that contact with than this immortal plant?

This wonderful herb proclaims its own divinity. In overcoming its own death, it demonstrates its power. In brilliant visions it shows its divinity. In fantastic sayings or celestial songs, it teaches with moral force. In pulling back the curtain of time and revealing the future, it shows itself as a god. In driving illness from sick bodies, it reveals divine healing powers. In its joy, the heart is gladdened. This was a divinity a man could know. A god, meant to be worshiped by being killed and used, but no wrong done. You have slain a god yet he lives again! An awesome god who lies down its life, for those who love him, and takes it up once more, a god that tastes death, yet is deathless itself, a completely guilt free gift, straight from the creator of all things.

Now, let's leave what the ancients thought of this herb of immortality, and return to the experiments and what this herb can teach us today.

An extraction with food source liquids in an effort to produce an extra pleasant drink, would invariably lead to resurrection. Like all fungi, the herb is temperature sensitive and prefers warmth to resurrect in the mentioned 3 days.

Amanita muscaria must be a very effective antibiotic producer. All experiments were carried out in a non-sterile environment, in an effort to replicate the ancient conditions. So these experiments must have been subject to spores and bacteria in massive amounts. Yet not one appeared to be contaminated with any other life form. I have even carried out the whole process, from extraction with grape juice to resurrection, to its greatest growth, outdoors during the late summer, with only a cloth covering the jar's mouth to keep bugs out. Not only could the ancients have carried out the resurrection, I believe, anyone can! This simple experiment should be proof to anyone that *Amanita muscaria* is producing one or more exceptional antibiotics.

All the resurrected cultures were dried to convert Ibotenic Acid to Muscimol, these seemed to possess the same gram for gram potency that they originally had.

The foods used were grape juice, boiled barley water and honey water. Grape juice was chosen because it was readily available to ancient people in the Middle East and Mediterranean Basin.

Barley cooked in an excess of water, the water strained off and then used, was chosen because of it being mentioned in the Rig Veda. Barley was also one of the earliest cereal grains to be cultivated, so, it would be available very early in history.

Honey was available to humans long before agriculture. Honey is the most widely available sweetener in

Eurasia. It would, of course, have been used to sweeten any beverage. The honey was diluted in water to create a slightly sweet tasting solution before being used.

When the cultures resurrect, and while growing, the appearance is one of mold. An aggressive, hairy, bluish gray to white mycelium completely covers the pieces of specimens. It looks like it should smell very bad; however, this is not the case! Resurrected with grape juice, there is a slight vinegar smell that transforms into one of the most delightful flowery fragrances I have ever smelled. Barley water produces a much heavier smell that while strong, is not offensive. Resurrected with honey, the smell is flowery, mild and pleasant. This is important to show that the resurrected *Amanita muscaria* would not offend man. There is no reason a person, acquainted with the herb, would not try the resurrected specimen in an extraction.

It is obvious that the food sources I chose are also the food source liquids used for another fungus cultivation, yeast, yielding wine, beer and mead. All three were known from ancient to modern times. But in light of the new knowledge of the herb of Life's resurrection, can we be sure that all ancient wines etc. were really alcoholic? A comparison of modern wine, ancient wine and a grape juice, *Amanita muscaria* extract is in the Question of Wine in the following chapter.

Observations on the Resurrection of Amanita muscaria

This Fungus needs oxygen, sealing it in an airtight jar; results in slow or no growth, with the production of very smelly chemicals. All the experiments were covered with a cloth or paper towel. This seemed to supply enough oxygen and keep the humidity levels high enough.

In the dark, the mycelium is actually a pure snow white; this quickly changes on exposure to light, to a silvery, bluish gray color. Occasionally there is a brownish tint. The pieces of the original specimen invariably turn dark, from a dark brown to almost black; they also grow back together into one piece. After this mycelium has been observed a few times it is easy to recognize, it is very distinctive in appearance and the color change from light is another identifying mark.

This plant likes warmth, with 60 deg. F. to 80 deg. F. being suitable for growth. Resurrection in three days requires 65-70 deg. F. After the mycelium starts to grow it will continue until it runs out of food and or water; this can take several weeks, I just let them grow till they stop. Do not shake or handle too rough while it's growing and don't place the jar in direct sunlight, it can be burned.

Amanita muscaria is a very hardy life form; I have resurrected dry specimens that were powdered before extraction, plus, those actually crushed, while full of grape juice, these were reduced to slime, and still resurrected! Although in both instances, it took slightly longer to resurrect these abused ones.

Once resurrected, the dried fungus returns to a living state much quicker than it does in the case of the specimen. Subsequent resurrections easily happen within three days. In order to prevent the extract from becoming charged with living chemicals, I only extract dried resurrections for half the time of specimens. (12 hours max!)

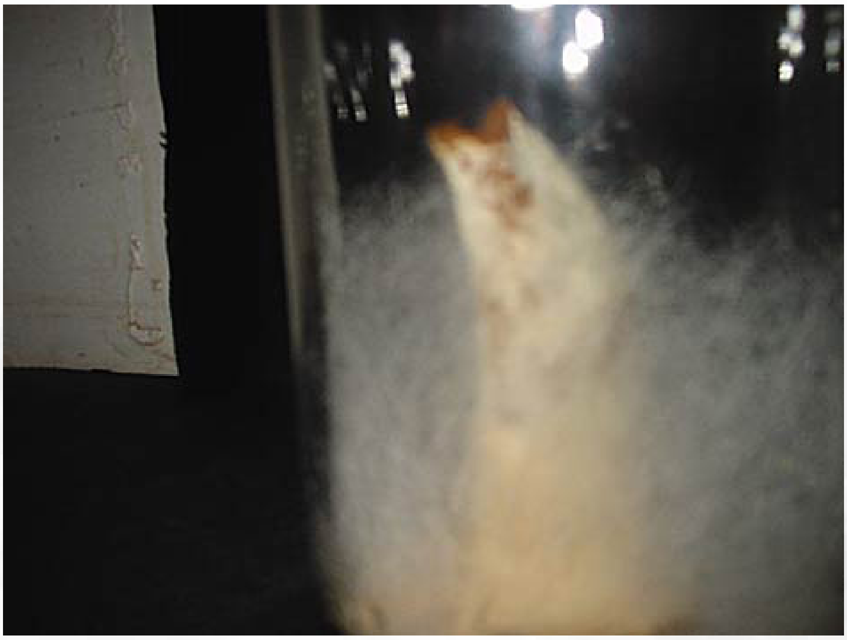
Drying the resurrections is necessary to convert Ibotenic Acid to Muscimol. Dry the same as a specimen. It can also be dried in the jar or bottle it grew in. Simply remove paper or cloth cover and place jar in a warm oven 120 deg. F. until dry. This reduces the handling damage to the mycelium considerably.

I believe that the natural ability of *Amanita muscaria* to resurrect allows it to; one, take advantage of food on the surface of the forest and two, be consumed by animals and distributed over a wide area.

Since almost any organic matter on the surface such as leaves etc is capable of being consumed by *Amanita muscaria* the Mushrooms ability to actually reach out with its mycelium and eat its above ground surroundings under certain weather conditions must give it a certain advantage.

Amanita muscaria mushrooms are routinely consumed by a large number of animal species such as slugs, squirrels and other rodents, opossum, raccoon, deer and the occasional human. When the mushroom is digested and then passed as feces the spores germinate and the mycelium will use the feces as a concentrated source of food. When *Amanita muscaria* is fruiting it is not uncommon to find fresh deer feces with what certainly appears to be *Amanita muscaria* mycelium sprouting several inches long. Since animals can move a considerable distance and the *Amanita muscaria* mushroom spores are getting a concentrated food source as a head start this ability has considerable survival value. In this the mushroom is acting just like most fruiting plants, which give animals food in return for their dispersing the plant's seeds over a wide area.

In these instances the *Amanita muscaria* mycelium that is exposed to the environment develops spores similar to those produced by the simpler fungi. Under the microscope there are small balls along the length of the exposed mycelium, which turn black when mature. Each of these tiny balls containing several hundred clear spores, and there can be thousands of these balls in even a tiny *Amanita muscaria* culture.



A single stem of dried *Amanita muscaria* on the third day after hydration, just starting to resurrect with long white mycelium plainly visible to the naked eye. Below is the same stem a few days later.

13. The Question of Wine

In answering the resurrection question, perhaps another mystery of the ancient world may be solved. That being the question, "What on earth were they drinking and calling wine"? Ancient wine was radically different from modern wine in many ways; so this is really an interesting question.

First, it should be established that ancient wine was intoxicating. It was, ancient sources stating that four drinking cups of wine caused intoxication. These cups have been recovered in great numbers from archaeological sites throughout the ancient world. The ones I have seen are about 4 to 8-oz. capacity. They are not usually much bigger than this but there are exceptions, of course. Consuming 16 to 32 oz. of modern wine would obviously cause intoxication. This modern wine is, however, consumed straight, and this is the major difference between modern and ancient wines. The ancients always cut their wine with water and not just a little water either. One part wine having two to ten parts water added. Exceptionally strong wine could even be cut twenty to one. The most common ratio mentioned being three to four parts water to one of wine. There is simply no way an alcoholic wine could be reduced with water in these ratios and still be active! So, if the ancient wine could not be alcoholic, what was it?

The addition of the water was considered essential to the process. Drinking undiluted wine was reputed to cause death, definitely another major difference between modern and ancient wine. The most common theory to explain this difference is shown below.

The technology of ancient wine making (open fermentation in crocks or vats) would only produce a six-percent alcohol content. This would be quickly reduced to acetic acid (vinegar). Ancient wine was produced exactly the same as modern vinegar. So, a stable vinegar solution was probably the basis of ancient wine. Vinegar is, however, not intoxicating. One explanation is that vinegar was used as a vehicle for carrying other drugs. Dried drug plants such as poppy (opium), datura, henbane, etc. being extracted with the vinegar. (With the possible exception of opium and ephedra, none of these other plants would really be pleasant in their effects.) Vinegar would then preserve these drugs in solution. This would allow bottling, transport and use months or years later. Drug plants, herbs and spices were also added to the wine in the mixing bowl when the water was added. Such drugged wine was probably used in the ancient world, and, before this rediscovery of the resurrection of *Amanita muscaria*, a very logical conclusion.

The resurrection does, however, suggest a different scenario; simply add a given weight of dried *Amanita muscaria* to your grape juice, etc. in an open crock. The antibiotic action of the herb suppresses competition for the juice. After a certain time, the juice is full of *Amanita muscaria* chemicals. It may be possible to then bottle and transport without spoilage. The presence of a small amount of living *Amanita muscaria* culture in the juice would also tend to inhibit spoilage.

The specimens can be left in the empty crock to resurrect and then grow. After this resurrection is dried, it can then be reused. After one or two growth cycles the culture would be completely unidentifiable as *Amanita muscaria*. This culture may be capable of living through many generations of men; long enough that the culture's true origin may be lost.

I believe that this is one of the main reasons for these sacred stories of the virgin birthed hero that does miracles; dies as a sacrifice; resurrects and becomes immortal; these are stories both sacred and wide spread and they contain a description of the only life form on the planet that would do this! This knowledge would allow starting a new wine producing culture from the wild source.

There was nothing more sacred in the ancient world than their wine. Wine was the one and only god worshiped by the entire ancient world; consumed by Greek, Roman, Jewish, Armenian, Celtic, Persian, Babylonian, etc. etc. a comforter of king and slave. Could there be a more Sacred knowledge to preserve for the future than this?

If *Amanita muscaria* were really the source of the ancient wine, an extract would have to be capable of being diluted with water in a large ratio. To test this, 1/2 oz. of dried *Amanita muscaria* specimens was extracted with 16-oz. grape juice; the extraction lasted 8 hours. The straight extract was sipped and produced the usual effects; the amount consumed being about 4 oz.

Then approximately 1 oz. extract was diluted with approximately 3-oz. water; this actually tasted better than the straight extract. Several ounces of the extract were consumed diluted in various ratios of 2 to 6 water to 1 of extract. To my great surprise, the addition of the water actually made a great difference in the effect. The usual *Amanita muscaria* effects became instead purely psychedelic, very similar to Psilocybin or LSD!

This intoxication was much more pleasant than that produced by the straight extract; the dilution also seemed to increase the potency, exactly the opposite of every other drug extract on the planet, where dilution invariably leads to a weaker solution. Nothing in my years of researching *Amanita muscaria* was as surprising to me as this transformation! It came completely unexpected and was a very enlightening experience. This experiment was repeated several more times with exactly the same result. The ancient emphasis on dilution was really a practical application of chemistry. I feel fairly confident in stating that *Amanita muscaria* really was the source of at least some of the ancient wines.

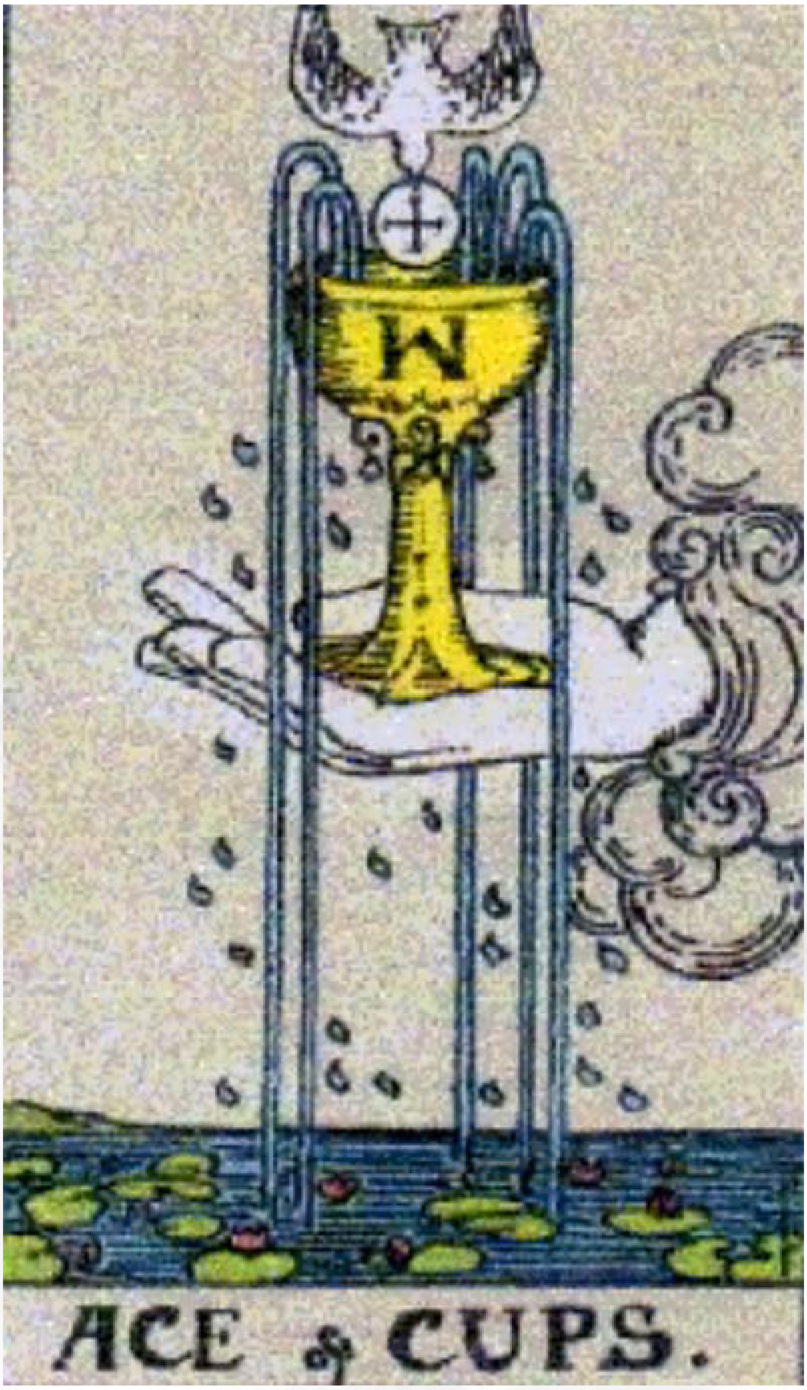
In trying to understand this transformation, I have developed a theory; Muscimol is a very polar molecule, I believe the oppositely charged ends link up and form long chains or other structures, I also believe these chains are released by the dried specimen into solution. Water is also a polar molecule and the sudden addition of a large amount of water breaks these chains into individual units of Muscimol dissolved in water. The long chains having the effects of the *Amanita muscaria* and the primary extract; while the dissolved individual Muscimol units having instead a psychedelic effect. This would explain the apparent increase in potency of the diluted solution. It is only a theory; but it is the best I can come up with, using only observed effects, a chemical structure diagram of Muscimol and reasoning.

This *Amanita* wine, after the addition of the water, was much more pleasant to me than anything alcoholic. In the ancient world this ability to be diluted and yet become stronger, would be another sign of divinity.

For details on creating an *Amanita muscaria* wine culture under modern conditions see chapter 15.

Shortly after The Sacred Secret was published, I was studying Celtic mythology and the Magic cauldrons in these Myths and their relationship with the Holy Grail. I soon realized that the Resurrection of *Amanita muscaria* solved the mystery of the Holy Grail, and after two years of research a separate little book was published titled "Natural Magic; Recreating the Grail" which is reproduced here in it's entirety; please note: since it was a separate booklet some info is repeated.

14. Natural Magic; Recreating the Grail



1909 Rider-Waite Tarot card, Ace of Cups, the secret of the Grail in a single image for those with eyes to see.

14-1. The Grail

The Grail has had hundreds of books written about it, yet not one book, till now, could prove what the Grail really is, what it does, or show you how to make your own Grail.

The Grail, a most precious, highly desired object of Knightly Quests, the Holy chalice that held Christ's Blood, and became magical as a result, a miraculous, mysterious, magical container of the Divine.

Legends and Stories of the Grail echo down through the Ages, whispering to us, of Power and Wisdom, living in a Cup! Stories of Wondrous Cauldrons and Magic Bowls whose drink of Healing, Poetry, and Inspiration never runs out! This is what this book is about.

The secret of the Grail is ancient, older than King Arthur, older than Christianity, far older than civilization itself. I had to follow the Grail into ancient prehistory to rediscover it's lost secrets.

The Grail is mysterious, yet it is real, it can be understood. The Grail is magical, yet like all magic once the secret is understood, it's very simple. The Grail is probably one of the oldest magic tricks known to man, but was absolutely baffling to early man when he performed it. This unexplainable Natural Magic astounded even the Wisest of Magicians.

The creation of a Grail involved the practice of the highest Magic known to early humanity. A Sacred, immortal, hallucinogenic plant was crushed and consumed as a beverage. Since the Plant is immortal it comes back to Life and lives in a suitable container, like your cup, perhaps forever. This is the technical magic of the Grail, plain, and simple. The real Natural Magic is the resulting symbiosis between all too mortal man and an immortal plant.

14-2. Soma, source of the Legends

Soma is just one of the many names for the Sacred Immortal plant used in creating the Grails, other ancient names are Ambrose (not-mortal) and Nek-tar (death-overcomer), names obviously based on the plant's resurrection and immortality. Soma itself means the pressed one, from the crushing of the plant in the preparation of the magic drink, in the Soma ceremony. One other ancient name for this sacred plant that deserves special mention is Maga (the Great Gift) Maga is the root of the modern words magic, magi, and magician.

Two modern names in English for this fungus are its scientific name *Amanita muscaria* and its common name the Fly Agaric; both names describe its power over flies. The *Amanita muscaria* is a large red or gold capped white mushroom with white patches on the colored cap. This pretty mushroom is commonly used decoratively, and is constantly found in Fairy Tale book artwork.

The *Amanita muscaria* is commonly found in temperate forests containing Pine, Spruce, Birch, Maple, and other tree species. *Amanita muscaria* has a worldwide distribution and is found on all continents except Antarctica.

Amanita muscaria varies in size from 3 to 8 inches diameter of the cap; it ranges in height from 3 to 10 inches, with up to 2 inches more stem below ground level. The cap color can range from a brilliant golden yellow to a deep blood red. The cap is covered with small white or off white warts arranged in a circular pattern, these are the remains of its universal veil. The underside of the cap is white or off white and has gills arraigned in a radial pattern, like the spokes of a wheel. If you remove the stem, the underside of the cap resembles a giant eye leading to ancient names like, the Single Eye. The upper stem has the remnants of the partial veil clinging to it like a small collar; this veil originally protected the gills. The very bottom of the stem is bulbous and usually has concentric rings or steps wrapped around it at ground level; this is the remains of the universal and partial veils attachment points on the base.

Like all the higher fungus (mushrooms etc.) the *Amanita muscaria* fungus occurs in two forms, the mushroom (the fruiting body) and the actual plant (the primal form) this primal form resembles common molds, such as bread mold. The primal form of *Amanita muscaria* can be huge; a single plant can cover multiple acres and weigh many tons. When the plant was used in the Soma ceremony the dried mushroom was crushed and destroyed, but the plant fragments, spores, and the magic drink it produced are capable of resurrecting and growing in the primal form.

My research with this plant leads me to believe that it would be impossible to perform the Soma ceremony with wooden or earthenware vessels and not have the plant resurrect and continue to live in them. The magic of the Grail can now be easily understood as a natural result of performing the Soma ceremony. This is truly Natural Magic.

14-3. Celtic Cauldrons and Magic Cups

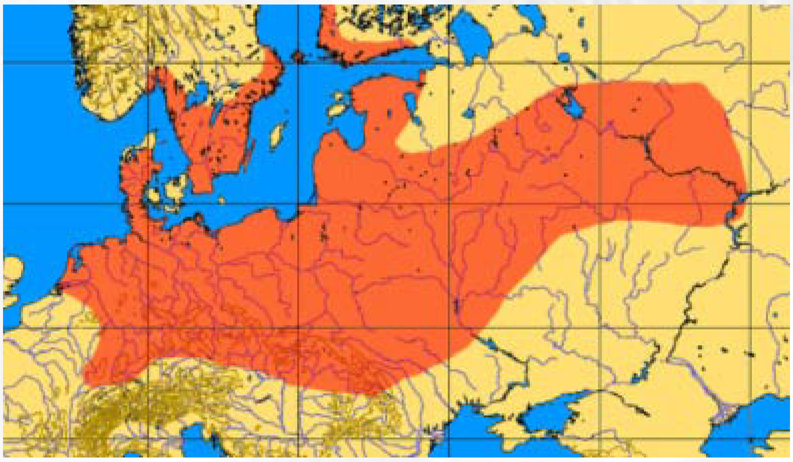
The Grail stories are now considered by many people to be Christian stories with the Grail being the cup that held the Last Suppers wine (a communion cup) or the cup that held Christ's blood. The truth is that the ancient Grail stories predate Christianity, and are old Celtic myths that were adopted by the Church. The word Grail comes from the Celtic "Greal", which means a brew of inspiration.

The Celtic origin of the Grail myths means that discovering Celtic beginnings may lead us to the Grails beginnings.

The people known to the modern world, as Celts are the Irish, Welch, Scots, and Bretons, all now living in or near the British Isles. Before the rise of the Roman Empire the Celts occupied a large part of Northern Europe, from Hungary through Germany and France to Ireland, Spain and Italy.

These Iron Age Celts are descended from a large group of Stone to Bronze Age cultures collectively known as the Corded Ware or Beaker People. This name was given to these people due to the earthenware drinking beakers and amphora found in male burials. These beakers are quite large (1.1 liter) and were impressed with cords before their firing. In the burials, the beaker was either in hand or close to it. Amphoras are large earthenware pots that are associated with the beakers. Other burial finds included flint and copper knifes, stone arrowheads, and wrist guards. One other item consistently found in these Warrior burials is perforated stone mace heads, hammerheads, and battle-axe heads. Leading some scholars to label them the Battle-axe people.

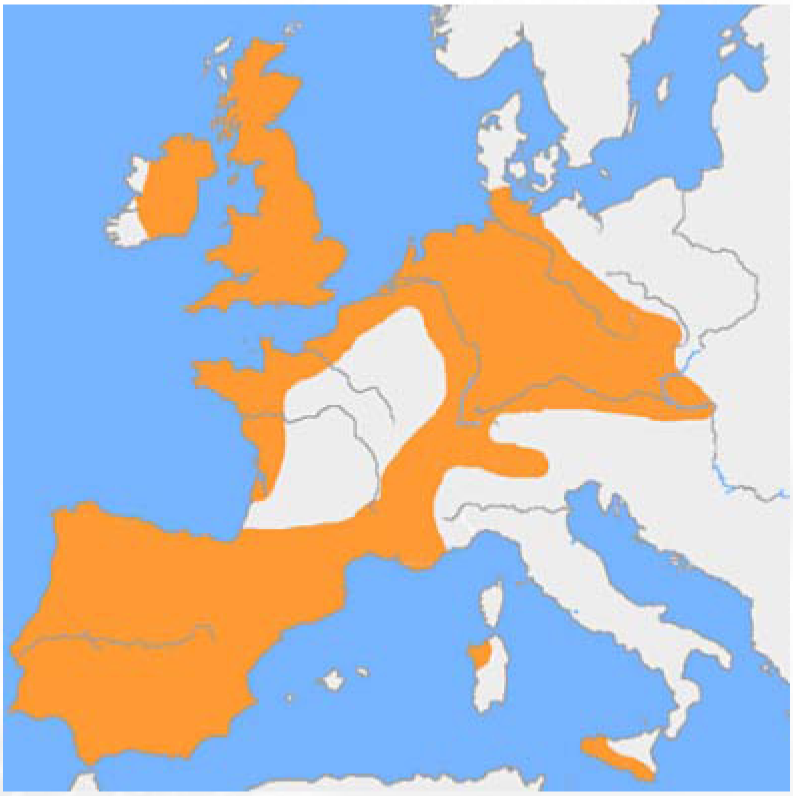
The Beaker culture extends back to 6,000 years before the present or 4,000 B. C. The Beaker people had horses, cattle, sheep, and goats and practiced agriculture, they possessed the wheel, plow and early metallurgy. By 2,000 BC they occupy all the territory the Celts are found in 1,500 years later. I believe the Beaker people are the source of the Grail myth and the ancestors of the Celtic and other European peoples.



Above area of the older Corded Ware culture.

We will never know what language the Beaker people spoke, they are simply too far away in time, and left us no known writings. The Celtic languages are part of a large language family called Indo-European. Languages in the Indo-European family are all related to each other and share a common point of origin. Modern Indo-European languages include Irish, English, German, French, Italian, Greek, Kurdish, Armenian, Russian, Iranian, and Hindi. This is only a small sample of Indo-European languages. Indo-European languages are spoken over a broad band of Eurasia from Europe to India. Further spread of Indo-European speakers has distributed it over much of the globe.

Below area of the Bell Beaker people.



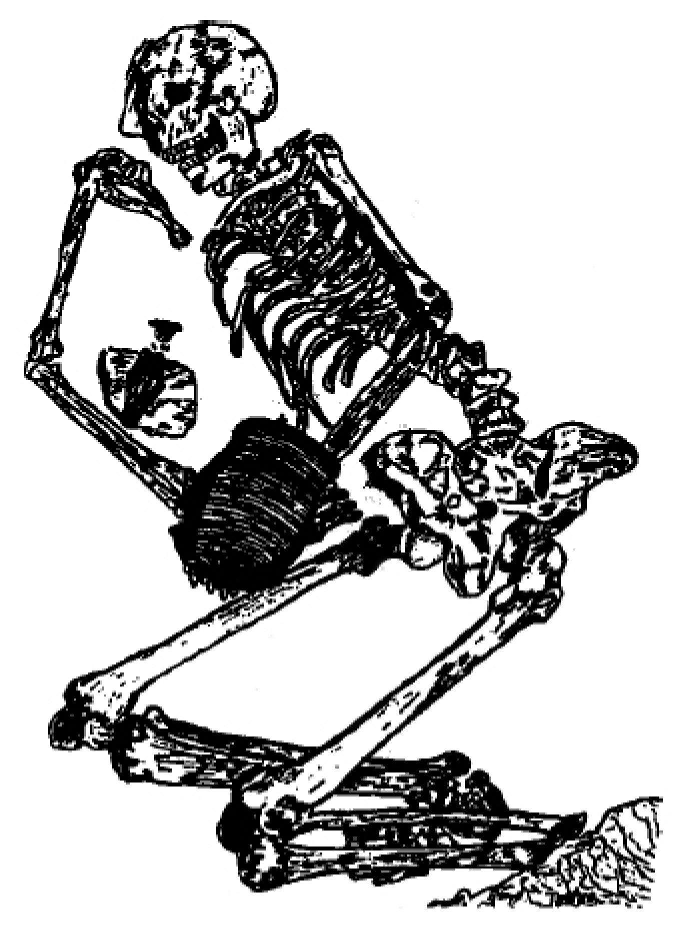
Since Indo-European has a point of origin, one can assume that at some early point, all the Indo-European speakers in the world were in one small area. If you find certain cultural traits and Legends common in the various descendents of the earliest Indo-European people those traits and Legends are from the original Indo-European speakers.

One such cultural trait and myth common to the early Indo-European peoples are Legends of a Divine Plant of Immortality which was processed into a Sacred Drink of Inspiration. This drink and the plant that produced it are known as Ambrose (ambrosia), Nectar, and Soma. Words found in both Greek and early Sanskrit (India). Our knowledge of the Soma ceremony is based on the Rig Veda (Praise-Wisdom) a book of Hymns composed by Seers and Sages. The Rig Veda is one of the largest and oldest texts in any Indo-European language; some of the Hymns may date back to 2,000 BC or older. Indo-European people expanding into Northern India in the Bronze Age composed the Rig Veda.

The Rig Veda has one overriding theme: Soma; one whole book #9 is completely about Soma and Soma is mentioned in almost every Hymn in the other books. Soma is obviously the source of the Wisdom, the ancient Seers and Sages were praising. Book 9 Hymns were sung as the Soma was being prepared and were an integral part of the Soma ceremony.

After the Soma was prepared it was poured into wooden cups to be consumed these wooden cups were owned by individuals who carried them to their grave. A man's wooden Soma cup was placed in his burial within easy reach if the dead man ever needed it. This is strikingly similar to the Beaker burials. When burial was by cremation the wooden Soma cup was placed on the funeral pyre, to accompany him into the afterlife. Large wooden and earthenware bowls were used in the processing of the Soma; these would also have the Immortal Plant living in them, just like the smaller cups or beakers. The amphorae in the Beaker burials correspond to these large Soma bowls; both are representations of the Magic Cauldrons, Pots and Bowls, found in all Indo-European Myth.

Bell Beakers recovered from beaker burials.



Typical Beaker burial, this one is from England, 2000 BC similar burials exist across Europe from Moscow to N. Africa all have elements in common, weapons, (in this case a copper dagger) male burial and the cord impressed Magic Beaker.

14-4. Proving the Theory

Ancient legends and archeology have given us a starting point, to attempt to recreate the Grail. In Science an unproven theory is just conjecture. To prove that any theory is true, evidence must be assembled from experiments. Experiments to be true must be repeatable by everyone and yield the same results, under the same conditions.

In the Resurrection Question (chapter 17) of The Sacred Secret, I detail my rediscovery of *Amanita muscaria*'s fantastic ability to resurrect. This fundamental rediscovery completely changes our understanding of ancient Religion and Magic, and provided the basis to really understand the Grail Myths.

My experiments in the Resurrection Question were carried out in glass canning jars or glass bottles. *Amanita muscaria* resurrected and lived in the glass no problem, but it didn't seem to be happy in there. Glass is a cold material; small animals may die of hypothermia if kept in a glass jar in even a warm room, it is also very slick, the fungus could not attach itself to the glass. Glass provided no nutrition for the fungus; all the glass resurrections were fed a food source liquid like grape juice or honey water.

I began some preliminary experiments on earthenware using some small terracotta pots called muffin pots available at a local Craft store. These pots are made in the same clay and shape as a common flowerpot minus the drain hole and are 3" in diameter Terra-cotta is a source of mineral nutrients which is why potted green plants usually grow much better in terra-cotta than in plastic, porcelain, or stoneware planters. Terra cotta is also porous and can hold a liquid food in itself till the *Amanita muscaria* uses it.

The fungus grew quite well in these small pots. These cups were used dozens of times and seemed to become more potent with each cycle of use. They did however have some major drawbacks; first they are tiny, holding only about 3 oz of fluid, second the wide-open mouth and shallow depth allowed them to dry out fast, placing one on top of the other, mouth-to-mouth helped compensate for this. Thirdly they were thin and fragile, and broke very easily. Lastly, the machine made inner surface was very smooth, it seemed that a more textured and porous surface, like ancient earthenware possessed, would be a much better surface for the fungus to grow on.

Tests on samples of stoneware and unglazed porcelain proved that the fungus would not grow well on these substances, the higher firing temperature leads to partial or complete vitrification, which resembles glass in its physical properties.

In summation if you place *Amanita muscaria* in a suitable terra cotta pot with a source of food it will resurrect and continue to grow on the walls of the pot perhaps forever!

14-5. Creating Your Own Grail

Creating your own magic Grail is easier than baking bread or canning fruit, simply follow the directions below to create your own Grail. But first you must understand some basic chemistry concerning *Amanita muscaria*. *Amanita muscaria* must be dried to become psychoactive; this converts a chemical called Ibotenic Acid to muscimol, which is the desired agent. When Ibotenic Acid is dried the chemical loses a carbon dioxide molecule and a water molecule to produce Muscimol. This chemical change can be reversed with Carbonated water so do not consume dried *Amanita muscaria* or the products of the Grail with Carbonated water (Beer, Soda, or bubbly wine like Champagne). To do so will at the very least nullify the mental effects and at the worst it can cause symptoms similar to fresh (undried) *Amanita muscaria* poisoning. These symptoms include nausea, vomiting, stomach cramps and extreme sedation resulting in a coma like sleep with no hallucinogenic effects!

Once you have a functioning Grail it will be used in a basic cycle of being filled with a food source liquid (Grape juice, Honey water, etc.) that feeds the fungus and is what you will consume. This liquid will set in the Grail for 4 to 12 hours; it is then poured off and drunk. The Grail will then be allowed to set empty for a week or more to grow and dry and can then be reused, this cycle can be repeated indefinitely.

To create your Grail you first need a suitable terra cotta pot or bowl, the ancients Beakers ranged from a tall vase to shallow bowl shapes, so the shape doesn't seem to matter, but a vessel you can see and reach into is very convenient. The terra cotta vessel should be at least 16 oz (500 ml) in capacity to make it worthwhile to use. Pottery shops or Garden supply stores are good places to look for a suitable pot, remember it must be terra cotta just like a clay flowerpot. Porcelain, stoneware, or any pot that's glazed inside or out cannot be used. If you wish you could try to make your own terra cotta pot, just remember to fire it at the lowest temp (700 to 800 degrees Celsius) higher temperatures cause vitrification and make the pot useless for a Grail. Some Colleges, Craft Stores, or pottery supply stores offer classes in ceramics, for most people this is easier than doing it all themselves. The Pot must also have enough of a rim to secure your cloth cover described below.

You will need a suitable thin cloth to cover the Grail whenever you are not pouring liquid into or out of the Grail. In the Grail legends the Grail was always covered with a cloth. In practice any cloth that is thick enough to keep fruit flies out of your Grail can be used. Cotton, or Linen works well but even polyesters can be used. The main requirements are that it keeps fruit flies out, easily lets oxygen in and helps keep the humidity level high for a couple of days to allow the fungus to grow. This cloth should be secured with a string or rubber band around the top of your Grail to keep it in place. It also helps to have two cloth covers for each Grail so that one can be washed and dried while the other is covering the Grail.

The next thing you need is the dried *Amanita muscaria*; this can be found in the forests or can be ordered from suppliers listed in Supplies and Sources in the last chapter. Most people will find it much easier to purchase this plant than to hunt it on their own, and that is what I recommend. If you wish to hunt this plant you will need a good field guide to mushrooms and you should also read my book The Sacred Secret for instructions on how to handle *Amanita muscaria* after its picked.

The last item you need is fungus food, this can be as simple as a store bought bottle of pasteurized Grape juice, Honey dissolved in boiling water, or any beer recipe without the yeast and hops. For most people the Grape juice will be the most convenient food to use since it is pasteurized before being bottled it is not likely to introduce any contamination into your Grail. Other bottled juices like Apple always seem to have other things added (corn syrup or chemicals) and I don't use them. If you wish to use a fresh juice it should be brought to a temp of 190 deg F in a double boiler to pasteurize it and it should be filtered and cooled before using. If you wish to use honey or a beer recipe it must be brought to boiling and then allowed to cool while covered, let it cool to room temp before using it in your Grail, adding hot liquid can cook the *Amanita muscaria* living in the Grail. The Honey or beer solution should also be filtered through a coffee filter to remove solids, or in the case of honey, any undissolved globs which if left on the fungus when it dries will kill it with sugar. All the food the fungus receives should be dissolved in solution or in microscopic pieces. This way it grows quickly, runs out of food quickly and enters its dormant state. While the plant is in its living phase it excretes Ibotenic Acid, which dries into muscimol on the surface of the fungus, it's this muscimol, which is extracted, with the next feeding.

Once you have the 4 items listed above you can begin the creation of your GRAIL There are 2 easy ways to create your Grail.

#1 Fill your terra cotta pot with clean drinking water and determine the volume of the pot by pouring the water into a measuring cup. Rinse the inside of the pot and place upside down to drain; this step is common to both methods.

The simplest way is to place 14 to 28 grams (1/2 to 1 oz) of dried *Amanita muscaria* pieces per liter (quart) of the pots volume, into your rinsed out pot. To this add your chosen room temp liquid food, place on the cloth cover, and leave undisturbed for 6 to 12 hrs in a warm area. Now you pour off all the liquid leaving the pieces of mushroom in the pot. Arrange the pieces on the sides of the pot in an open pattern to prevent the pieces from compacting (in a tall vessel you may have to lay it on its side to do this), recover with your cloth cover. See the next chapter on using the Ambrosia you just poured off. Place in a warm dry area that has air movement. In 3 days the pieces of mushroom and the walls of the pot should start getting fuzzy as the *Amanita muscaria* reverts to its primal form. This mycelium will be white or gray and continue to grow until it runs out of food and or water this can take several weeks. After the mycelium stops growing it will dry and shrink, the Grail will be ready to use again when the outside of the pot is warm and dry to the touch, the pieces of mushroom are hard, and the mycelium is shrunken back. Basically this is a two-week to one-month cycle, especially in a large pot.

The second method is to use the same ratio of *Amanita muscaria*, 14 to 28 grams (1/2 to 1 oz) to 1 liter (1 quart) of your pot's volume. This is ground to a powder and poured into the pot, then add the room temp liquid food, cover, and let it sit 6 to 12 hrs. Strain off the Ambrosia leaving the dregs and a small amount of liquid, return any filtered powder to the pot. Rotate the pot to evenly coat the inside of the pot with the now soggy powder. This powder will resurrect and create a thin layer of living *Amanita muscaria* on the inside of the pot. Because its in a thin layer it can go through a complete cycle of use in 7 to 14 days and works very well in small pots of a liter or less.

No matter which method you choose to use; adding a small piece of mushroom or some ground powder to the Grail occasionally with the liquid food seems to boost the cultures growth and keep it healthy.

Drying the Grail is as easy as placing the Grail in front of a small fan in a dry room temp area for at least 3 days before using. A fan can't over dry the Grail so it is the safest way to dry it. It is very important that the Grail be dry before using to produce the desired effects.

14-6. Using the GRAIL

Using your Grail is now a very simple procedure that any one can do! Place the dried Grail on a plate or other waterproof base, remove the cloth, and fill with your chosen liquid food. Recover the Grail with its cloth and let it set for 6 to 12 hrs after which time you uncover it and pour out the Ambrosia that the Grail has produced. Recover the Grail and let it sit in a warm room temp for the next 7 to 28 days at which time it is ready to use again.

The Ambrosia that you have poured off should be diluted with at least 2 parts water to 1 of Ambrosia before being consumed. As the Grail is used it will grow in thicker and thicker and become more potent with each cycle of use, dilute with more water as it becomes stronger. Eventually it can be diluted at a ratio of 3 or 4 parts water to 1 part Ambrosia. This dilution is very important to produce the desired effects; undiluted Ambrosia is actually less potent than the properly diluted Ambrosia. Remember do not consume any CARBONATED beverages (Soda, Beer, or bubbly wine) when consuming your Grail's Ambrosia, or let anyone else do so!

The intoxication produced by drinking the diluted Ambrosia is very pleasant for most people; in small doses it is similar to alcohol while larger doses produces a psychedelic effect. Undiluted Ambrosia in large doses can produce a confused mental state that most people do not find as pleasant as properly diluted Ambrosia. (The best antidote to this condition is drinking water.)

As your Grail gets older it should eventually lose its white or gray fuzzy look and start looking similar to a lichen (a tough leathery fungus found on rocks and trees) it will usually be white, gray or black, sometimes all three of these colors are found simultaneously. Also as your Grail gets older it should develop a unique fragrance depending on its own genetics and the foods it has been fed, this fragrance is also mentioned in the Grail legends were the Grail has a spicy aroma. All of the ones I've created smell kind of like mint or flowers when they reach this stage.

The ambrosia produced by your Grail or dried *Amanita muscaria* specimens is a living culture and will resurrect into the Primal form in 3 to 5 days. Because of this fact a Magic Grail can multiply and create another Grail, simply using a terra cotta vessel, as a drinking cup for Ambrosia will cause it to eventually become a Grail capable of creating its own Ambrosia; truly this is Magic.

You now posses a Magic Grail; it is possible that this Grail can live for many more years; properly taken care of it may last the rest of your life! Your Grail is however a Living organism and it must be treated as such. Do not expose your Grail to high temperatures, or let it freeze when it's in its living state. Always check the condition of your Grail before using, if it smells bad do not use it. Check to see if it has other colors on it; yellow, green, red or blue, may be a sign of contamination especially if it also smells bad. Remember to always keep the Grail covered with its cloth and keep it were rodents cannot get into it. Do not leave your Grail full of liquid food for more than 12 hrs it will start to drown, it needs air just like you do.

Recipes

Notes on Water:
Like beer, coffee, and tea making, the quality of the water you start with has a large impact on the taste of the final result. Use the best water you can find. Do not use chlorinated water in your Grail; chlorine is a poison to funguses. Do not use "hard water" in your Grail; the chemical deposits it contains can be harmful to the *Amanita muscaria* living in the Grail. Use fresh reverse-osmosis water or distilled water in all the recipes. (Remember not all bottled water is reverse-osmosis, some bottled spring water is very hard and should not be used.) If it is impossible to get these waters, well or city water may be boiled for 20 minutes to sterilize it, remove the chlorine, and leave the hard water deposits in the boiling pan rather than in your Grail. Cover the boiling pan and let cool to room temp filter through a coffee filter before using

1. Bottled pasteurized grape juice in a quantity to fill the Grail should be purchased, always open a new bottle for each use to prevent contamination. This can have as much as 10% water added before being used. Use at room temperature. This creates the Wine of Dionysus.

2. Frozen concentrated Grape Juice can be used if mixed with good water. Mix according to the directions on the container.

3. Honey at the rate of up to 3 fluid oz. per quart (90 ml per liter) of water is dissolved in boiling water, remove from heat, cover and let cool to room temp. Stir before using to make sure the honey is completely dissolved, if it isn't, it should be filtered through a coffee filter to remove any globs of honey. Honey has the widest range of flavors of any single food you can use. Ancient honey contained much more pollen than modern honey usually does; cooked pollen from certain plants could be a very nutritious food.

4. Barley, organic human food grade Barley is added to water at the rate of 4 fluid oz. (1/2 cup) per 5 cups=1.25 quart (1.25 liter) in a cooking pot. Bring to a boil, reduce heat to simmer, cover and cook for 45 to 60 minutes, add water to replace volume, bring back to boiling. Remove from heat, leave covered till cool, and filter through a coffee filter to produce a clear fluid. This recipe can also be combined with the honey recipe to produce better tasting Ambrosia.

5. Any home brew beer recipe can be used in your Grail remember to delete the yeast and hops from the recipe, and to filter it before using at room temperature.

These recipes are all based on recipes found in the ancient texts such as the Rig Veda; other foods could be experimented with if you want to.

The most convenient food is the Pasteurized bottled Grape juice, you don't need a stove and cooking pots to use it, just open the bottle and carefully pour it into your Grail. It is however a good idea to vary the foods you feed your Grail, so the *Amanita muscaria* has a wide range of nutrition. Please note: any clear fluid extraction following a grape juice extraction may appear dark colored due to the previous grape juice; it is however harmless and the ambrosia is as good as ever.

14-7. Conclusions

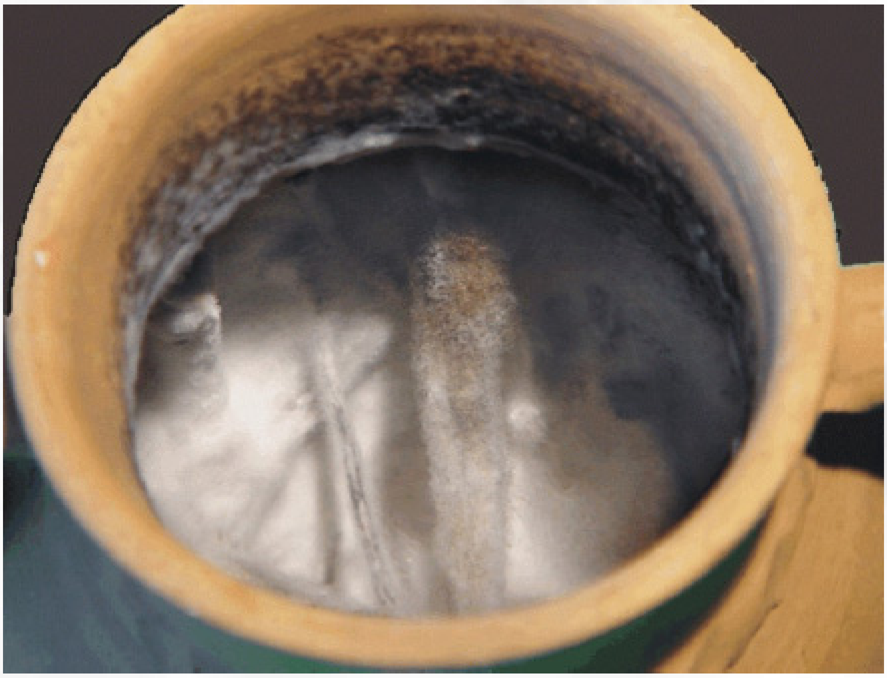
The corded ware, beaker culture and the Grail religion lasted more than 2500 years, eventually spreading from east of Moscow to Scandinavia, Scotland, Ireland, England, Germany, France, Italy, Spain, Portugal, and North Africa, an ancestral culture of all of Europe and beyond.

The theme of the Beaker burials is echoed in the Grail myths the combination of warriors and Magic vessels are the two main elements common to both. Legends of Magic pots and cups producing a Magic drink are recorded by writing as soon as writing appears in Europe, continent wide ancient legends that last until today.

There are two ancient claims for the Grail of Legend that should be of special interest to modern people. First the Grail could reputedly heal any non-fatal wound and cure any illness! Second, those who possessed the ancient Grail had extremely long life spans. Attributes that the Grail shares with *Amanita muscaria* in the ancient legends. As shown in The Sacred Secret, to be able to resurrect *Amanita muscaria* must be producing exceptional antibiotics.

The *Amanita muscaria* as the Ambrose, Amarta, Amrita, the Nek-tar of the Gods is an Indo-European heritage encoded in our languages, religions, myths, and folklore. This immortal plant and its accompanying Magic vessel are the source of ancient legend and Myth. It was called Maga, "the Great Gift," the very root of our modern word magic! Those who carried the Great Gift were called "Gift bearers," the root of the modern words Magi, Magus, and Magician. The Grail is one of *Amanita muscaria*'s greatest Gifts to mankind, a magical never ending source of inspiration, enlightenment, healing, comfort, joy, and by it's very existence, astonishment!

The Grail when recreated with *Amanita muscaria* matches the Grail of ancient legends perfectly. From it being a never-ending source of wisdom and inspiration to having the spicy smell of the Grail of legend. I believe that the fantastic ability of *Amanita muscaria* to resurrect and live in a wooden or terra cotta cup or bowl is the source of the Grail legends, and of all Eurasian stories of magic cups or bowls. It is very unlikely if there is any other explanation for these ancient legends except *Amanita muscaria* and its natural ability to do the seemingly impossible. *Amanita muscaria* is NATURAL MAGIC.



A photo of one of the Author's Grails containing resurrected *Amanita muscaria*. Now you can see why the Grail of legend could not serve a coward.

15. Growing the Eucharistic Bread and Wine in quantity

This section tells you how to create both the Living Bread and the Sacramental Wine; which are the sacred sacraments of Christianity. Any one who understands the importance of the Sacraments in the New Testament Bible understands that consuming the Living Bread and the Sacred Wine is the basis of Christianity.

While terra cotta was used anciently to culture *Amanita muscaria* it does have some major drawbacks when compared to glass. Terra cotta can become contaminated with other fungi or bacteria and the only solution is to discard the vessel. Which may explain the massive amount of discarded pottery at some Eur-Asian Archeological sites, in many cases the pottery was deliberately broken before discarding. A practice which would keep anyone from using a contaminated vessel by mistake.

Glass however can be sterilized with both heat and chemical methods to insure the minimum contamination.

Making the Living Bread

Gospel of John 6:48-51
48. "I am that bread of life.
49. Your fathers did eat manna in the wilderness, and are dead.
50. This is the bread which cometh down from heaven, that a man may eat thereof, and not die.
51. I am the living bread which came down from heaven: if any man eat of this bread, he shall live for ever: and the bread that I will give is my flesh, which I will give for the life of the world."

The living bread is perhaps the greatest of *Amanita muscaria*'s Magic tricks and can increase the supply of the Sacrament several hundred times in a very short period of time.

With the Grail only a small quantity of *Amanita muscaria* mushroom mycelium is produced at any one time, with the living bread a large amount of mushroom mycelium is grown out on cooked Barley in three days or less, and after it is dried, it can be used just as if it were the dried *Amanita muscaria* mushroom.

The grain chosen has a large effect on the finished product; Wheat, Rye, and Oats do not work as well as Barley; which contains a larger amount of protein compared to the other grains. Rice should never be used due to an ever-present contamination by a green mold that always develops on cooked rice. All Grain in general is contaminated with all kinds of bacteria, yeasts, smuts, and other fungi, these are usually present at harvest but the levels of contamination may increase dramatically due to improper storage.

Many people make a big deal over so called "organic" grain, which is actually not as good for making the living bread as the more refined Barley sold for human consumption. Basically the outer hull of the Barley grains is removed in a process called pearling this exposes the inner starch to the *Amanita muscaria* Fungus and greatly accelerates the growth, also a large amount of contaminating fungi spores; bacteria and yeast are removed with the seed hull during pearling so a much cleaner grain is produced by this operation.

Barley that still retains the seed hull will take more time for the *Amanita muscaria* fungus to colonize and can actually double the time it takes to grow compared to the more refined Barley, this extra time needed for growing and the large amount of contaminants on this type of Barley greatly increases the chances of contamination.

You should be aware that sometimes "organic" Barley is claimed to be "Pearled" this is however not a true statement unless the seed hull is removed; at which time it cannot legally be sold as "organic whole grain" Barley!

The Barley used should resemble white rice in color, with a dull abraded surface, and has only a small line of yellow running down the grains length, if the Barley grains are smooth, shiny and yellow it still has its seed hull and should be rejected for use.

The desirable refined Pearled Barley is actually very easy to find with the dried beans at almost any supermarket, and is usually sold in 1 lb bags, which are very convenient to use, all the instructions and times mentioned here assume the use of this Pearled Barley.

Cooking the Barley is the next step and is a very important factor in the success of the operation. The cooked Barley grains should be slightly rubbery and can be fluffed into individual grains, to provide a light airy structure in the grain for the *Amanita muscaria* fungus to grow through.

It is best to cook only 1 lb of dry Barley at a time, cooking larger amounts will cause the bottom grain to become almost like glue from the weight of the grain above it. The cooking pot should be at least 11/2 gal (6 quarts) in capacity and have a tight fitting cover; a wide bottomed pot is to be preferred over a narrow pot of the same capacity.

Since the weight to volume ratio of different lots of Barley grain can vary greatly I always use a 1 to 2 ratio of Barley to water by weight, so for a 1 lb bag of Barley I use 2 lbs of water = 1 quart, for reference 1 pint of water weighs 1 lb, for those on the metric system, use 500 grams Barley and 1 liter water.

Into the pot add 1 quart water, cover and heat till boiling, open cover add 1 lb white pearled Barley, stir, replace cover and turn heat down to a low simmer, cook for 45 min, turn heat off and leave covered till cool, approx 2 hours; do not stir or mess with it till it is cool.

Remove cover and using a fork lightly scrape the surface of the grain to release individual grains, continue to scrape all the grains free from the mass, when you get to the bottom of the pot there is usually some grain stuck in a layer of glue like residue carefully break this up into very small pieces of 1 to 3 grains and mix it into the rest of the grain.

At this point you should add the inoculant in small doses to the grain in the cooking pot, mixing it into the fluffed grain very thoroughly. After it is inoculated, load the grain with a large serving spoon into the jars chosen about 2 inches deep, place a coffee filter over the jars mouth and secure with a rubber band.

The inoculant is made by using a 1-ounce bottle with a cap, into which 1/4 fluid oz (fill bottle 1/4 full) of dried powdered *Amanita muscaria* cap is placed, fill the bottle with room temp water that has been boiled, and let it sit for 3 hours, shake well before using it on the grain. I usually make up the inoculant before I start cooking the Barley. This small amount of inoculant is perfect for 1 lb of the dried Barley when cooked, using more inoculant can add too much water to the cooked grain and cause problems.

The jars should be wide mouth canning or storage jars, from 1 pint to 1 gal in size, my personal preference is the 1 gal wide mouth jars, 3 to 4 of which can hold the cooked grain from 1 lb of dry Barley, the smaller jars hold about 3/4 to 1 cup of cooked grain each and require about 9 to 12 jars to hold all the grain. It is very important to practice good sanitation and clean the jars thoroughly with detergent, rinsing thoroughly, and if necessary soaking with a chlorine bleach solution.

Place the loaded inoculated jars into the grow area you have chosen, it should be room temperature (65-72 deg F) with some air movement and no direct sunlight on the jars, a dark area is to be preferred but not at the expense of air movement. The grow area must be easily cleanable and kept clean, it must also be free of other molds, for example using a moldy smelling basement as a grow area is just asking for contamination.

If everything goes right by the 36-48 hour, small areas of white hairy growth should be plainly visible to the naked eye scattered through the grain. Under ideal conditions the Fungus will completely colonize the grain between 60 to 72 hours after being placed into the jars. When the grain is completely colonized the *Amanita muscaria* fungus will have grown out of the surface of the grain 1-2 inches, and be pure white to a light gray white in color. It is very important to harvest the living bread at the right time, if the culture is allowed to grow past this point the top will quickly turn black with a massive amount of spores.

It is very important to inspect these cultures very carefully for contamination by other life forms such as bacteria using both sight and smell, other fungi can usually be seen as a difference in color or structure of mycelium, while bacteria can be detected by a strong sour smell. Contaminated cultures should not be used for human consumption and the jars that contained them should be either cleaned and boiled in water for 20 min or soaked with a strong bleach solution, before being reused.

Because the *Amanita muscaria* fungus can colonize the cooked Barley in a short amount of time contamination is usually not a problem, however temperatures above 78 deg F in the grow area can accelerate the growth of bacteria while slowing the growth of the *Amanita muscaria* mycelium and lead to contamination.

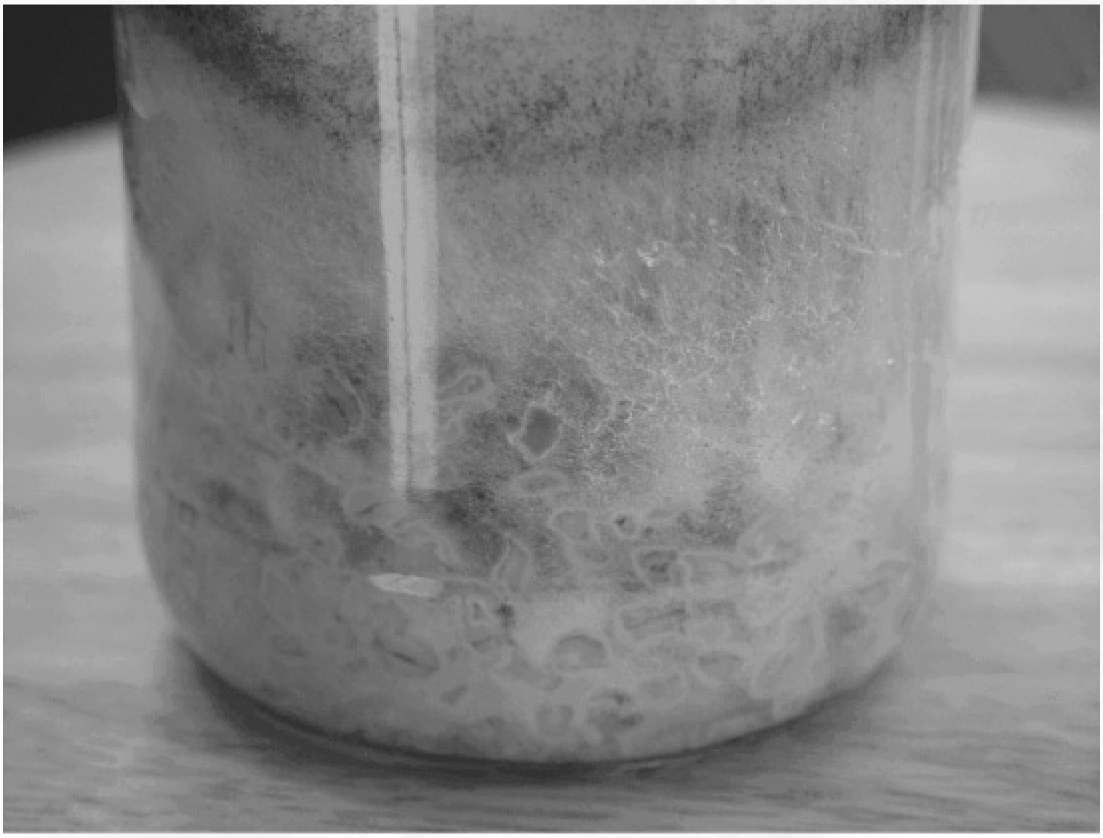
When the cultures are harvested they must be dried before they can be used, I use the same food dehydrator with a built in temperature control that I use to dry the *Amanita muscaria* mushrooms. The cultures can also be dried in an oven set on the warm setting with the door cracked open slightly.

The cultures should be dried completely dry and it is better to dry it too long than not enough, breaking the cultures into pieces speeds up the drying process considerably. When the cultures are completely dry place into sealable plastic bags or glass jars, in a very short time it will generate a very pleasing aroma, and become quite fragrant. The Living Bread is much better tasting than the Barley it was made from with a very satisfying malt type flavor.

The dried Living Bread can be ground into flour and sifted through a fine mesh strainer and used in a wide variety of recipes such as brownies, cookies, cakes, Banana and other sweet breads. The Living Bread flour can be used cup for cup instead of regular flour in your favorite recipes, the only real difference in the Living Bread recipes is to leave out all the salts, I don't add table salt, Baking Powder, or Baking Soda, and I cook everything I make at 300 to 325 deg F as Muscimol breaks down at 350 deg F. or higher.

If the dried Living Bread is cracked into pieces or ground to a coarse flour it can be cooked in boiling water like a regular hot breakfast cereal such as Oatmeal or Grits, and creates what I call the true Breakfast of Champions, with milk and honey added it is extremely tasty and really brightens up the day.

A very tasty Ambrosia can be made from the Living Bread by simply soaking the ground flour in cool drinking water and adding honey or sugar to sweeten, this can also be prepared as a hot drink by simply heating the water containing the Living Bread Flour, I use about ½ cup flour in 1 quart water, but the exact ratio isn't real important. You can also add the Living Bread flour to grape juice or other fruit juices and create a Living Bread Wine, in just a few minutes.



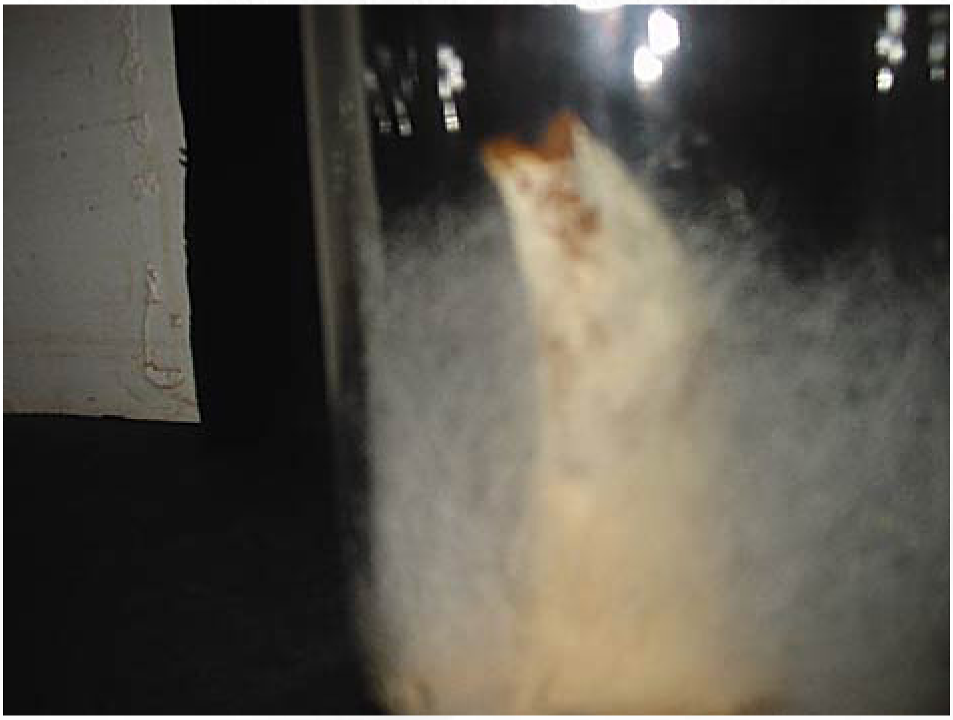
Amanita muscaria growing on cooked Barley.

Making the Sacramental Wine

The Gospel of John 15: 1
1. I am the true vine and my father is the husbandman.

The purpose of this is to instruct you in culturing your own alcohol free, sulfide free, Ambrosia Wine simply and cheaply at home using concentrated fruit juices, some simple equipment and the Ambrosia plant (*Amanita muscaria*).

Amanita muscaria is immortal, all the culture techniques used by the ancients and by us today are based on the fact, that *Amanita muscaria* mushrooms can be dried, stored dry for a long time and when re-hydrated with water magically returns to life in three days as mycelium.



A single stem of dried *Amanita muscaria* on the third day after being re-hydrated with water and now growing mycelium, this is what the *Amanita muscaria* mycelium should look like.

In Soma: Divine Mushroom of Immortality, Wasson cites reports of Siberian Tribes who fermented *Amanita muscaria* with various berry or fruit juices, diluted honey or with juice from a certain type of sweet grass. Many Tribes used these fermented juices for curing upset stomachs and other medicinal applications along with its use as an intoxicant.

The wines of the ancient Greeks and Romans were also capable of being used medicinally; Homer in the Iliad, states that undiluted Wine was used on battle wounds, (like an antiseptic) something that modern wine is never used for.

Unlike modern alcoholic wine, the Ancient wines of western Eurasia had to be diluted with a large quantity of water before being consumed; in fact, ancient sources state that consuming a large quantity of undiluted ancient wine could cause death. This wine was diluted with large ratios of water; ranging from one part wine with two to fifty parts water added.

These potent wines are mentioned in ancient literature such as Homer's Iliad (800 BC) and were produced from very ancient times into the late Roman Era (500 AD). At this time, the production seems to cease, along with any more mention of these very special wines in the literature of the day.

To give the reader a quick background on culture techniques that we will use here, we will look at the beginning of scientific microbial culturing. This uses glass bottles, a simple micro pore filter, and sterilization by the use of heat. Using these simple scientific techniques developed over the last one hundred years the average reader can easily culture the Ambrosia wine. There are significant benefits to this modern approach over the ancient methods, such as using just the tiniest amount of dried mushroom to start a culture and the high productivity with a very low contamination rate.

Louis Pasteur (1822-1895) is credited; with the important discovery that the air is full of microorganisms and their spores, which cause the spoilage of food and can cause diseases of plants, animals and man. He used a very simple experiment to prove his theory and this experimental technique is the basis of modern pure culture techniques for growing fungi, bacteria, yeasts, even plant, and animal cells in a sterile environment as a pure culture.

In Pasteur's experiments, glass bottles partially filled with beef broth; milk or other foods that quickly spoiled in the open air were prepared. The bottles mouth was then plugged with a tight wad of waterproof cotton, the bottles were placed upright into a hot water bath and cooked to a temperature that killed all microbes inside the bottle, the hot air and steam generated in the bottle passing through the cotton wad. By cooking the bottles properly, the contents would not spoil, even if kept for months. The cotton plug did not seal out air so this was fundamentally different from canning which requires an airtight seal.

Pasteur further showed that if you removed the cotton plug from a sterile bottle exposing the sterile food contents to the microbe and spore filled outside air for even a few seconds, then reinserted the cotton plug, the contents always spoiled in a short time. Microscopic examination of the contents of the spoiled bottles always showed microorganisms, which were absent from the contents of the still sterile bottles.

Pasteur's secret to creating a sterile environment with food and oxygen inside of the bottle is the cotton plug, which is sterilized during the cooking process by out flowing steam and hot air. The now sterile cotton plug becomes a micro-pore filter capable of filtering out all the microorganisms and their spores from the outside air that re-enters the bottle on cooling.

It should be obvious that if the right foods for a certain microorganism were prepared this way and then inoculated with even a small amount of that microorganism culture, that culture would flourish in this artificial environment without any competition from other microorganisms. If the inoculating culture is completely free of other contaminating microorganisms it will grow into a pure culture in the bottles. The cotton plug allowed oxygen-using cultures such as Fungi, to obtain oxygen from the outside air without allowing contaminating microbes into the pure culture.

Making the Sacred Ambrosial Wine is a simple process that requires only some easily obtained supplies and some commonly available equipment.

1. Dried *Amanita muscaria* mushroom caps, you need low temperature dried *Amanita muscaria* mushroom caps that will be used as the inoculant. If you purchase dried *Amanita muscaria* mushrooms, the higher grades are usually worth the extra money. If you picked and low temperature dried (120 degrees F or less) your own *Amanita muscaria* mushrooms, the caps of the best specimens should be saved separately for use as inoculant. These dried caps should be inspected carefully for dirt, pine needles etc, which should be removed, before they are ground into a fine powder. The small coffee grinders work very well and are inexpensive enough that one can be dedicated to only grinding *Amanita muscaria*. The inoculant should be ground fine enough (like flour), that it to floats on the surface of the juice.

2. Glass bottles or jugs. Next, you need glass bottles of from 1 pint to 1-gallon capacity such as juice bottles of all sizes, beer bottles, wine bottles etc. however, bottles with a tapered neck are better than bottles with a short neck for plugging with the polyfill. The size of the bottles you can use, is determined by the size of the cooking pot you have. Clear glass bottles are preferable to brown, green or blue bottles to culture in since you can easily see the culture inside. I prefer; the clear glass 1-gallon jugs, they can hold up to three quarts of juice for culturing, they are the largest size bottle that is commonly found and yet they are small enough to easily handle when hot. New bottles need to be cleaned before using, with detergent and hot water and rinsed repeatedly to remove all traces of the detergent. Recycled juice and especially beer and wine bottles should be filled with a hot bleach solution of 1 fluid ounce of bleach for 1 quart of water, filled all the way to the top,

sealed with the proper cap and left for several days, rinse the bleached bottles well before using. Always inspect the bottles carefully for cracks and chips which can cause breakage of the bottle during the heating and cooling cycle of pasteurization.

3. Polyfill, Mr. L Pasteur used specially prepared waterproof cotton, which would not absorb the water or steam generated by the cooking process to plug the bottles and create a micro-pore filter. Today waterproof cotton is very expensive, the last time I priced some from a science supply store it was over $35.00 a pound.

There is however, a superior substitute called Polyfill, which is a polyester fiber that resembles loose cotton, available from craft and fabric stores as a pillow stuffing. The polyester fiber is waterproof, not biodegradable, and is easily sterilized with the heat of pasteurization. A few dollars will buy you a big bag of Polyfill, which will last through a lot of culturing.

To use as a micro-pore filter, a polyfill wad is rolled into a ball about 3 or 4 times the size of the bottles mouth and pushed in with a twisting motion. The plug must be tight fitting and as the ball of polyfill is twisted into the bottle, the plug should get longer. It is a good idea to practice plugging an empty dry bottle of the kind you are going to use, to get the right feel before you actually start culturing.

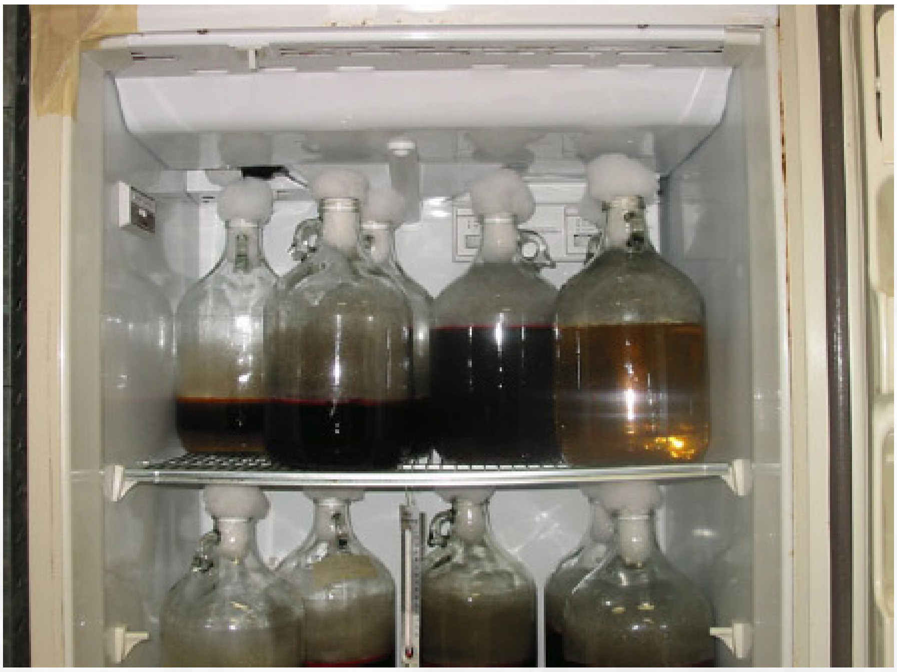
4. Cooking pots, you, will need two cooking pots, a small stainless steel cooking pot of about 11/2 gallon to react the finished wine and a large one for pasteurization.

To pasteurize the juice in the bottles you need a hot water canner with a basket or a suitable sized cooking pot and a holed metal plate or stand to hold the bottles off the bottom of the cooking pot, I use the metal stand that came with a pressure cooker. The cooking pot must be large enough diameter to hold the bottles and deep enough to match or cover the juice level inside the bottle. Ideally, the pot should be deep enough to cover with a lid that does not touch the polyfill of the plugged bottles inside. You can use an aluminum pot to pasteurize the juice filled bottles, but never let grape juice or the wine touch an aluminum pot, utensil or foil. Acid containing liquids like grape juice will quickly dissolve aluminum into solution and create a poisonous product. Always use stainless steel or the new tempered glass cooking pots to react the finished wine.

This is the Authors pasteurization equipment, a large pressure cooker pot, with the metal stand to hold the bottles off the hot bottom of the pot. There is no need to use pressure I simply use a stainless steel salad bowl for a cover that is tall enough to not touch the bottle's polyfill plug.

5. An accurate waterproof thermometer that is easy to read in the temperature range of 150-195 degrees F made of glass or stainless steel, I prefer Stainless steel, as it is unbreakable. You will probably have to rig a wire to hold the thermometer at the proper depth in the water.

6. A growing area, you need an area set aside to place the bottles during the time they are growing. The temperature needs to be from 64 to 74 degrees Fahrenheit and stable without fast or wide swings in temperature. A cabinet or closet will work, as well as an old refrigerator that has the doors shimmed open a small amount. The growing area should be easy to clean and thoroughly cleaned before being used the first time.



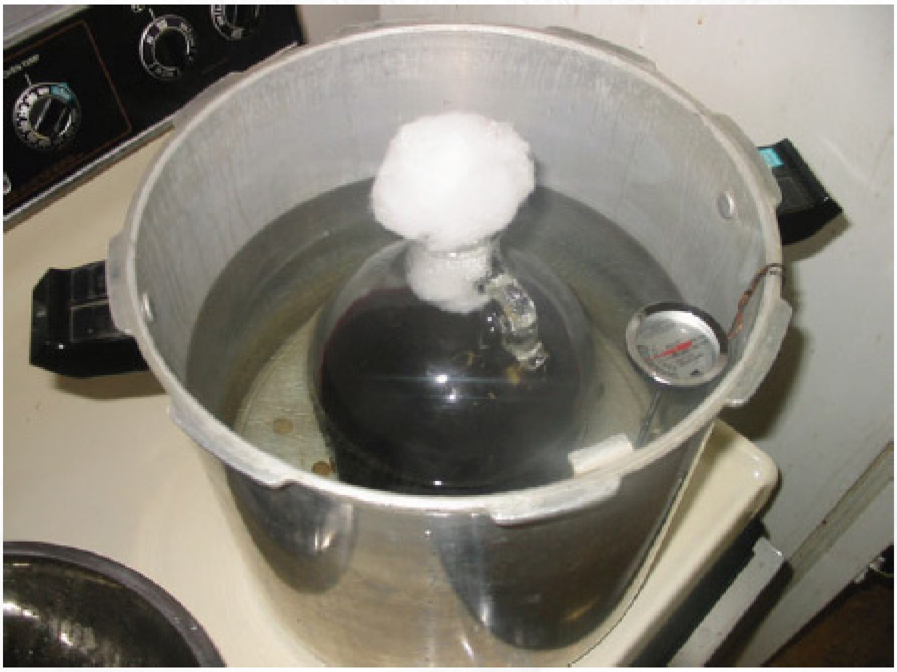
This is the Authors growing area, in an old refrigerator with the doors shimmed open slightly to provide for air circulation.

7. Fruit juice, you can purchase grape or other fruit juice in the frozen concentrate form, at any grocery store. For best results, this juice must be pasteurized, before being used to culture the Ambrosia wine. I prefer the frozen concentrate for several reasons, one, it's much cheaper than bottled juice, two, by pasteurizing the juice in the polyfill plugged bottle that is going to be the growth chamber, a more sterile situation is created than simply pouring bottled juice into a clean bottle. Mix the thawed frozen concentrate juice with water according to the directions on the juice container. If you are using small bottles, mix the juice in a pitcher or a large bottle and pour into the small bottles.

Take the cleaned bottles or jugs you have chosen and fill to the start of the jugs shoulder or approximately ¾ full i.e. a quart bottle will hold 3 cups of juice and 1 gallon will hold 3 quarts. It is important to leave a suitable air space in the bottle and the largest surface area possible on the top of the juice to support the *Amanita muscaria* fungus; which grows on the surface of the juice.

Carefully wipe the inside of the filled bottles mouth and neck with a clean piece of paper towel to remove any juice that might contact the polyfill plug. Juice left on the bottle's neck or mouth may become a source of contamination and it gets sticky enough after pasteurization to pull fibers out of the polyfill plug when it is removed for inoculation. Now, plug each of the filled bottles with a tight fitting wad of polyfill.

Place the polyfill plugged bottles containing the juice into your cooking pot on a metal stand or in the canning basket, and add cool water to the pot until the water in the pot is just about 1 inch above the level of the juice in the bottles. Place the pot on a stove and slowly heat the water at medium or medium high until the water in the pot reaches 175 deg F (use a thermometer) turn heat down and hold at 175-185 deg F for 30 minutes.



A polyfill plugged 1 gallon bottle containing 3 quarts of grape juice ready to be pasteurized.

Carefully remove the hot bottles from the water bath and place on a folded towel or a thick layer of newspaper to prevent the bottom of the bottles from breaking due to thermal shock. If you are going to pasteurize more bottles pour out the hot water from the pot and replace it with cool water as placing cool bottles into hot water can also cause breakage from thermal shock.

Cooled to room temperature the bottle is ready to inoculate.

Once the pasteurized bottles have cooled to room temperature, they are ready to inoculate; this step must be performed quickly to avoid contamination of the pasteurized juice, the whole operation of inoculation should take less than ½ second per bottle. Remove the polyfill plug straight up and hold about one inch over the mouth of the bottle and inoculate the bottle with approximately ½ an aspirin tablet size of the powdered inoculant for a gallon jug or ¼ that amount for a quart bottle. The point of a knife works well to pick up and handle the small amount of inoculant needed. The inoculant should be dropped onto the surface of the juice, quickly replace the polyfill plug into the mouth of bottle. Carefully place the bottles into their growing area without sloshing the fluid inside.

Inoculating the Grape juice with powdered *Amanita muscaria*.

The juice is now inoculated with ground *Amanita muscaria* caps and the polyfill plug is being replaced.

In 1,5 to 3 days, the *Amanita muscaria* mycelium should start growing large enough to see with the naked eye and in a few more days will become a thick mat of long white mycelium floating on the surface of the juice with fine filaments reaching into the juice.

In 3 to 4 weeks for the quart, sized bottles or 1 to 2 months for the gallon sized bottles depending on temperature and the amount of sugar in the juice the Wine should be ready. Young *Amanita muscaria* mycelium is white, as the culture ages the mycelium will start to turn gray and finally a very dark gray that almost looks black. This color change seems to be related to the amount of sugar in the juice. If you want a sweeter fruitier tasting wine harvest the wine when the mycelium turns uniformly light gray. When the mycelium is dark gray most of the sugar has been consumed and the *Amanita muscaria* mycelium will start eating the fruit flavor right out of the juice. It takes some time to develop a feel for when to harvest the wine to get the quality you want. Beginners can use a simple rule; to allow one week for starting and then add one week for every inch of the juice depth inside the bottle. Starting with an equal amount of juice, a narrow tall bottle will always take longer than a wide bottle filled a few inches deep.

The long white to dark gray *Amanita muscaria* mycelium growing on pasteurized grape juice, converting the juice into the Sacred Ambrosial Wine.

When you think the Wine is ready pour off the juice through a funnel plugged with a small amount of clean Polyfill sitting in another bottle of suitable capacity. If the *Amanita muscaria* fungus consumed all the sugars and other food in the juice, the raw wine will keep in a bottle at room temperature for a long time without going bad, being similar to vinegar, as ibotenic acid is chemically a form of acetic acid.

The Wine has two phases the raw and the reacted. The raw wine as poured from the fungus culture contains mostly Ibotenic acid and has an acidic taste. Consuming the raw Wine in any large quantity causes stomach upset for most people and it is not as potent as the same wine after it is reacted. Small quantities of raw undiluted Wine (1-4 oz) can be consumed medicinally for stomachaches, fevers, colds, or flues and can also be used as an antiseptic on wounds, but it stings like alcohol.

To react the raw Wine, the ibotenic acid is converted into muscimol; by heating in an open stainless steel pan or better yet, a stainless steel double boiler to more than 195 degrees F stirring constantly. This process drives off the CO_2 molecule that is chemically bound to the ibotenic acid molecule, converting it to muscimol and creates a sweeter tasting wine that is 4 to 10 times stronger in potency than the acidic form. The released CO_2 forms very small bubbles, which can easily be seen in the wine when it is heated to the correct temperature. Once the wine starts to simmer and release steam, at temperatures above 195 degrees F, most of the CO_2 is gone and the reaction is now done. From sea level to 3000 feet this temperature recommendation holds true, at higher elevations, the upper temperature needed to release the CO_2 molecule will be lower.

The reacted Wine should be diluted with water, in the ancient ratios of 2-20 parts water for every part Wine before drinking. The properly diluted Wine is more pleasant to drink and more potent than the undiluted Wine.

An alternate method of reacting and diluting the raw wine in one operation is to fill a stainless steel cooking pot with three or four times the volume of good drinking water for every volume of raw wine. Cover the pot and heat this water to a rolling boil then pour in the raw wine and stir, continue to heat at a lower setting, stirring regularly, until the temperature reaches more than 195 degrees Fahrenheit. Shut off the heat, cover and if it is going to be used that day let it sit until cool.

If you wish to bottle this, reacted and diluted wine for later use; pour the still hot (180+ degrees F) wine into cleaned fruit juice bottles or jugs; filling all the way to the top of the bottle and then cap the bottle with the proper cap. On cooling, a vacuum is created inside the bottle and if the seal between bottle and cap is airtight, the cap should be depressed by the outside air. If the cap did not depress on cooling then an airtight seal was not formed and the wine in that bottle should be used immediately. Only store bottles whose caps were depressed, and if a stored bottle is later found to have a raised cap do not use the contents.

I only use recycled bottles, which have the screw caps, to store the finished wine, the screw cap being much simpler and less expensive than other ways of sealing a pasteurized bottle.

If you wish to use beer bottles to store the pasteurized reacted wine, you need a hand capper and caps available at homebrew beer supply stores.

Wine bottles that use corks can also be used to store this reacted and pasteurized wine and the equipment needed to cork the bottles is also available at homebrew and wine making supply stores. However natural corks have many problems including a specific bacterium found on about 1 in 5 corks that while harmless to humans, can ruin the taste of the stored product. Natural corks may not seal airtight and the cork and the bottles mouth must be dipped into melted sealing wax while the bottle is still hot, to insure an airtight seal.

Artificial plastic corks are available from the same homebrew and home wine supply stores. These plastic corks were developed specifically to overcome the shortcomings of natural corks and are preferable to the natural corks in every way but appearance.

To keep for long-term storage the bottled wine should be stored in a cool dark area to prevent light damage to the wine, which can change the flavor and color. Dark green or brown bottles are more resistant to light and help preserve the flavor better than clear glass bottles.

To serve the bottled diluted reacted wine simply open the bottle and serve at room temperature or chill before serving. Raw wine must be reacted before serving, see the instructions above for details. Reacted undiluted wine must be diluted with water before serving, the ancient ratios of 3 or 4 parts water to one of wine is usually adequate for most Ambrosial wine.

The Ambrosial Wine stimulates the appetite and the taste buds, and it makes an excellent dinner wine. Food should always be served with this wine, even if it is just snacks like cheese and crackers.

I have used other juices to grow the *Amanita muscaria* culture on including white grape juice, apple juice, pineapple juice, and orange juice. These last three juices do not contain as much sugar as grape juice, and unless sugar is added during mixing, they are not as strong as the grape wine. Blueberries are related to bilberries, which have been recorded as being used in Siberia to culture *Amanita muscaria*, but I have not found a good source of blueberry juice yet. I think any fruit juice that is both sweet and acidic could be used to culture *Amanita muscaria* on.

If you have a very clean area to work in you can pull small clumps of mycelium from your wine cultures that are being harvested, with a piece of wire bent into a hook, flame the wire before using. These clumps of mycelium can then be used to inoculate freshly pasteurized juice to start the cycle over again.

The ancient Christians served their version of the Sacramental Wine when they celebrated the Agape, or "love feast", and the Communion. The Eucharist Wine and the Living bread are the foundation stones of the earliest Christians beliefs. With these Sacraments made from the "Bread from Heaven", they healed the sick, uttered prophecies, spoke in tongues, and were themselves spiritually reborn by consuming the "Flesh and Blood of God".

16. Gods, Books, Myths and Folktales

This small section describes the ancient Gods that are obviously *Amanita muscaria* and their accompanying texts. By reading these ancient texts the reader can begin to do their own research on this fascinating ancient interaction between mankind and *Amanita muscaria*. I have included some of my favorite quotes from several of these texts, and in some cases my own commentary on a particular passage.

I encourage the reader to study this ancient knowledge as in depth as they wish, as this was the greatest knowledge the ancient Eurasian world possessed. These ancient people were our ancestors and the Old Sacred Knowledge they possessed is our inheritance and our birthright.

17. The Rig Veda

Soma and the Holy Grail

The Rig Veda is the world's oldest and largest religious texts consisting of just over one thousand Hymns, containing over ten thousand verses divided into ten books. These Sacred Hymns are usually dated to the late Bronze Age, but many of these Hymns may actually be considerably older. The name Rig Veda means Praise (Rig) Knowledge (Veda), Veda is an ancient Indo-European root word that in many modern Indo-European Languages still means knowledge of a sacred nature. The Rig Veda is written in an archaic form of Sanskrit and is a foundation document in the studies of ancient Indo-European languages.

Traditionally the Rig Veda was hand written with ink, on Birch bark sheets that are then bound with wooden covers painted red. The Birch tree is not found on the plains of India and the Birch bark is imported from Kashmir and the Himalayan mountains. Birch trees are well known to be symbiotic with *Amanita muscaria* and explain the link of this Holy Book made of Birch bark and *Amanita muscaria* as the God Soma.

The drinkable, Immortal, living God, Soma, is mentioned in almost every one of the thousand Hymns as the preferred drink of both Gods and men. There are one hundred and fourteen Hymns specifically about Soma in book nine of the Rig Veda plus a few Soma hymns scattered through the other books of the Rig Veda.

These Sacred Hymns were composed by Soma intoxicated "Seers and Sages" living very intimately with nature and are rich in naturalistic poetic imagery and animal metaphors and also contain a multitude of names that specifically refer to the God Soma. Many of these Soma hymns ring with ecstatic praise of the Soma plant/god/drink. Some of these Hymns poetically describe the mountainous natural habitat and brilliant Red or Gold appearance of the Soma plant. Other Hymns describe the processing sequence of the Soma plant into the Soma drink in the Soma sacrifice ceremony. A few Hymns also contain clear references to healings and increased life spans of Soma users.

The secret of Magic cups or what we would call the Holy Grail is found scattered through the Hymns of book nine. The Seers and Sages that composed this book were experts on the Soma plant/drink/god and loudly proclaim the secret of Soma's immortality, but to understand what they are saying, you have to know that *Amanita muscaria* is the real Soma plant and that it is capable of being completely dried, rehydrated, pounded between stones, and turned into the gods own beloved juice, every drop of this Ambrosia can resurrect, and create a magic cup or larger magic vessel simply by a terra cotta or wooden cup being used to hold Soma. Only, with this knowledge can you begin to understand what these Sacred Hymns are really saying regarding Soma the "Immortal God".

Soma and Healing

8 XLVIII 3-5 & 11,12

3. We have drunk Soma and become immortal; we have attained the light, the Gods discovered. Now what may a foeman's malice do to harm us? What, O Immortal, a mortal mans deception?

4. Absorbed into the heart, be sweet, O drop, as a kind father to his son, O Soma, As a wise Friend to friend: do thou, wide-ruler, O Soma, lengthen out our days for living.

5.These glorious drops that give me freedom have I drunk. Closely they knit my joints as straps secure a chariot. Let them protect my foot from slipping on the way: yea let the drops I drink preserve me from disease.

11. Our maladies have lost their strength and vanished; they feared, and passed away into the darkness. Soma hath risen in us, exceedingly mighty, and we have come to where men prolong existence.

12. Fathers, that drop which our hearts have drunken, Immortal in himself, hath entered mortals. So let us serve this Soma with oblation, and rest securely in his grace and favor.

8 LXVIII 1,2
1."This here is Soma, never restrained, active, all conquering bursting forth, a Seer and Sage by sapience.

2. All that's bare he covers over; all the sick he medicines, the blind man sees, the cripple walks."

1 XXIII 19, 20
19. Amrita is in the Waters; in the Waters there is healing balm: be swift, ye Gods, to give them praise. 20. Within the Waters - Soma thus hath told me - dwell all balms that heal, and Agni, he who blesseth all. The Waters hold all medicines.

9 LXXVI 4
4. "Monarch of everything that sees the sun light, Soma cleanses himself, triumphing over the Prophets, he made the Word of the Way to resound, he who is cleansed by the suns ray, he the father of poems, master-poet yet equaled."

Soma and the Grail

9- I- 1,2, 5,6
1. "In sweetest and most gladdening stream flow pure, O Soma, on thy way, pressed out for Indra, to be his drink.

2. Fiend-queller, Friend of all men, he hath with the wood attained unto His place, his iron fashioned home[1]."

5. "O Soma drop, we draw nigh to thee, with this one object day by day: To thee alone our prayers are said.

6. By means of this eternal fleece[2], may faith purify Thy Soma that is foaming forth".

9 III 1
1."Here present this Immortal God flies, like a bird upon her wings, to settle in the vats of wood".

9 XXVIII 1-6
1. "Urged by the men, this vigorous Steed, Lord of the mind, Omniscient, runs to the woolen strainer.

2. Within the filter hath he flowed, this Soma for the Gods effused, entering all their essences.

3. He shines in beauty there, this God Immortal in his dwelling place, Foeslayer, dearest to the Gods.

4. Directed by the Sisters ten, bellowing on his way this Steer, runs onward to the wooden vats.

5 This Pavamana[3], swift and strong, Omniscient, gave splendor to the sun and all his forms of light.

6. This Soma, being purified, flows mighty and infallible, Slayer of sinners, dear to Gods".

[1] The phrase "iron fashioned home" means a large carved wooden bowl that was carved with an iron chisel, iron was a very special metal in the Bronze Age, so in effect they are bragging.
[2] The "eternal fleece" is the mycelium of *Amanita muscaria*, which resembles sheep's wool, as you can see in the resurrection photos.
[3] Soma is called Soma Pavamana in most of the book 9 Hymns; Pavamana means self-purifying so Soma Pavamana is "the pressed one-self purifying". I believe that the Old Testament Bible's word "Manna" is a Hebrew version of Pavamana, perhaps inherited from long forgotten Indo-European ancestors or from the Persian religion of Zoroaster.

9 XII 1-8
1."To Indra have the Soma drops, exceedingly rich in sweets, have been poured, Shed in the seat of sacrifice.

2. As mother cattle low to their calves, to Indra have the sages called, called him to drink the Soma juice.

3. In the stream's wave wise Soma dwells, distilling rapture, in his seat, Resting upon a wild-cows hide.

4. Far-sighted Soma, Sage and Seer, is worshipped in the central part of Heaven, the strainer of wool.

5. In close embrace the drop holds Soma when poured within the jars, and on the purifying sieve.

6. The drop sends forth a voice on high to regions of air, shaking the vase that drops with honey.

7. The Tree whose praises never fail yields heavenly milk among our hymns, Urging men's generations on.

8. The Wise One, with the Sages stream, the Soma flows on to the dear places of the sky".

18. Zoroaster the Prophet and the Mazda Religion

Stone relief of Ahura Mazda.

The birth of the founder of the Mazda religion, Zoroaster or Zarathushtra, is variously dated from 6000 BC (Greek) to 600 BC (Sassnian). The later date seems more reasonable to me, yet there are many valid questions about the real age when Zoroaster lived. The theology developed by Zoroaster had a profound impact on the much later religions of Judaism, Christianity, Buddhism and Islam.

Beliefs found in Christianity today such as, heaven and hell, the resurrection of the dead, a last judgment, the coming of various saviors and an apocalyptic end of times are all found in the teachings of Zoroaster before they show up in any other religions. As the state religion of the Persian Empire, the influence this religion wielded in the ancient world was immense.

The Indo-European peoples who invaded Iran were closely related to the Indo-Europeans that continued on and invaded India. The Rig Veda's Soma cult was established in Iran at an early date.

Zoroaster did not create a new religion as many may think, he simply reformed this existing Vedic religion by doing away with the Vedic animal sacrifices, which he considered both cruel and wasteful and replacing it with the Fire Ceremony, while the ancient Vedic Soma/Haoma Sacrifice ceremony was elevated to the highest act of worship.

The use of Haoma (Soma) was integral to this religion, the concepts of the Mazda religion concerning Haoma's place in the universe are identical to early Christian concepts of the Christ.

The following is from the Encyclopedia Britannica (1991, vol. 26, pg. 789, Rites & Ceremonies):

"In Zoroastrianism haoma (Sanskrit soma, from the root su or bu, 'to squeeze' or 'pound') is the name given to the yellow plant, from which a juice was extracted and consumed in the Yasna ceremony, the general sacrifice in honor of all the deities. The liturgy of the Yasna was a remarkable anticipation of the mass in Christianity." "Haoma was regarded by Zoroaster as the son of the Wise Lord and Creator (Ahura Mazda) and the chief priest of the Yasna cult. He was believed to be incarnate in the sacred plant that was pounded to death in order to extract its life-giving juice so that those who consumed it might be given immortality. He was regarded as both victim and priest in a sacrificial-sacramental offering in worship. As the intermediary between God and man, Haoma acquired a place and sacramental significance in the worship of Mithra (an Indo-Iranian god of light) in his capacity as the immaculate priest of Ahura Mazda with whom he was coequal. The Mithraic sacramental banquet was derived from the Yasna ceremony, wine taking the place of the haoma and Mithra that of Ahura Mazda. In the Mithraic initiation rites, it was not until one attained the status of the initiatory degree known as "Lion" that the neophyte could partake of the oblation of bread, wine, and water, which was the earthly counterpart of the celestial mystical sacramental banquet. The sacred wine gave vigor to the body, prosperity, wisdom, and the power to combat malignant spirits and to obtain immortality."

19. Mithras

The Rock birth of Mithras from the egg.

"Mithras" is the Latin name of a Vedic god that the ancient Persians called "Mithra", and in the Rig Veda is called "Mitra". Mitra is one of the hundred plus names of Soma in the Rig Veda and means "the friend of all men". Mitra is an extremely old God, whose name first appears in writing in a peace treaty between the Hittite empire and the Mitanni in approximately 1450 BC. The Hittite and the Mitanni are both Indo-European peoples mentioned in the Old Testament Bible where the Mitanni are called Hurrians, which were claimed to be the best Charioteers in the world.

During the rise of Zoroastrianism in Persia the ancient cult of Mithra was suppressed for a short time, but rises again and is reincorporated into the Mazda religion of Persia.

After Persia; was conquered by Alexander the Great; the cult of Mithra spreads deep into the Greek and later the Roman world and was extremely popular with warriors. For a short time the Romans try to suppress the Mithras cult as a Persian subversion of the Roman people. The cult survives this persecution and begins to spread among the Roman elite and especially among the troops of the Roman legions, who spread it into the farthest reaches of the empire and beyond.

The cult of Mithras held its meetings and ceremonies, in small underground chambers called "Mithraeum". These chambers could only accommodate perhaps 30 people when the numbers of people became too large for that Mithraeum to hold another Mithraeum was established.

The Mithras cult was strictly male in membership and like modern Free Masonry the cults members were divided into a graduated hierarchy with 7 levels, only the highest grade of initiate could found a new Mithraeum. The ability of the Mithras cult to stay in small personal groups and still expand their total numbers was a key to their survival through any of the ancient persecutions. The cult of Mithras doesn't appear to be persecuted to any large extent by the official Christian Church, it seems they simply melted into Christianity.

Many modern Christians do not understand the tremendous influence Roman Mithraism had on early Christianity an influence that still exists today. Every Christmas Christians celebrate the birth of Mithras on December 25th and every Sunday they worship on Mithras sacred day. A lot of very old Christian Churches in Europe and the Middle East are built on top of even older Mithraeum, including the Vatican's Saint Peters Basilica, which has an ancient Mithraeum in its basement. Literally and physically the Soma God Mithras and the ancient religion of Mithraism, are two of the main foundation stones of Christianity

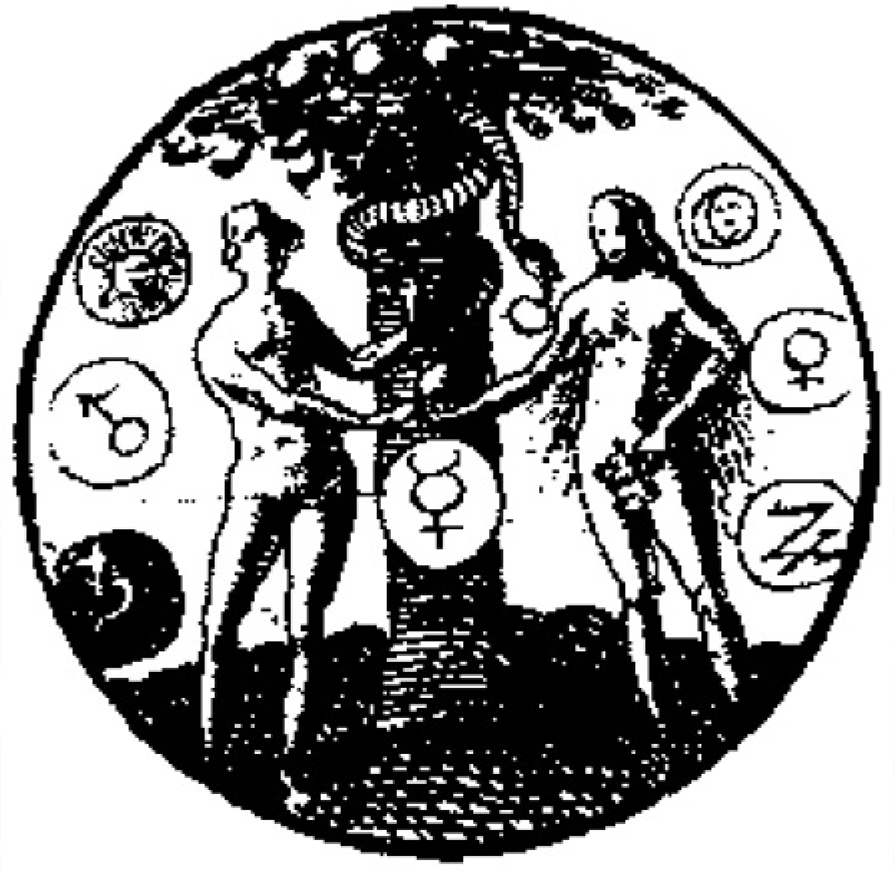
20. The Bible

What we call the Bible is actually two separate collections of books The Old Testament and The New Testament these books are widely separated in time and the languages in which they are recorded. The Old Testament was recorded in Hebrew on animal skin scrolls and as a collection of books dates no earlier than 600 BC although some of these individual stories may date back much earlier. The New Testament was written originally in Aramaic and Greek, recorded on papyrus in a codex format and the earliest individual letters and books still in existence date to no earlier than 140AD.

Although this large and varied collection of books are recorded over a fairly long time span with the influence of several different foreign cultural influences; there is one theme that is constant and that is consuming the Fruit of the Tree of Knowledge/Life.

In Genesis, Adam and Eve taste the forbidden Fruit of the Tree of the Knowledge of good and evil, and their eyes were opened and they became truly human. This is a concept carried through most of the other books until the Revelations of Saint John, the last book in the New Testament, where there is the river of the water of Life and the Trees of Life whose "leaves" were for the healing of the nations.

These books start with the consumption of a very special "Fruit" this same Fruit is consumed by the Seers (Prophets) in many of the Old Testament books, this is continued into the New Testament were the Fruit of the Tree of Life is re-elevated to the status of the Son of God, and must be tasted, consumed, and has existed from the beginning.



The Serpent of Wisdom, Adam & Eve, the Fruit of the Tree of Knowledge, from the Hermetic Garden.

Old Testament quotes.

Gen. 3: 3-7
"3. But the fruit of the tree which is in the midst of the garden, God hath said, ye shall not eat of it, neither shall ye touch it, lest you die.
4. And the serpent said unto the woman, ye shall not surely die.
5. For God doth know that in the day ye eat thereof, then your eyes shall be opened, and ye shall be as gods, knowing good and evil.
6. And when the woman saw that the tree was good for food, and that it was pleasant to the eyes, and a tree to be desired to make one wise, she took of the fruit thereof, and did eat, and gave also unto her husband with her; and he did eat. 7. And the eyes of them both were opened, and they knew that they were naked; and they sewed fig leaves together, and made themselves aprons."

Ps. 34:8
"8. O taste and see that the Lord is good; blessed is the man that trusteth in him."

Jer. 15:16
"16. I came upon the Words of God and I did eat them; and thy Word was unto me the joy and rejoicing of my heart"

Amanita muscaria when eaten dried or made into a cold-water extract has a flavor very close to Honey; this honey sweet taste is mentioned in the Rig Veda, the Yasna, and the Old and New Testaments.

In the quote below the source of this magic honey is a mountain dwelling life form that can suck "honey" out of rock. This life form can also eat a variety of human prepared foods and "drink" grape juice.

Deut 32: 13
"13. He (God) made him (Soma) ride on the high places of the earth, that he might eat the increase of the fields; and he made him to suck honey out of the rock, and oil out of flinty rock.

14. Butter of kine, and milk of sheep, with fat of lambs, and rams of the breed of Bashan, and goats with the fat of kidneys, of wheat: and thou didst drink the pure blood of the grape."

Ps. 81:16
"16. He should have fed them also with the finest of the wheat; and with honey out of the rock should I have satisfied thee."

Ezekiel 3: 1-4
"1. Moreover he said unto me, Son of man, eat that thou findest, eat this roll, and go speak unto the house of Israel.
2. So I opened my mouth, and he caused me to eat that roll.
3. And he said unto me, Son of man, cause thy belly to eat, and fill thy bowels with this roll that I give thee. Then did I eat it; and it was in my mouth as honey for sweetness.
4. And he said unto me, Son of man, go, get thee unto the house of Israel, and speak with them my words."

Here we see that the Honey sweet food is closely associated with prophecy and creates the ancient prophets.

Isaiah 42:18-20
"18. Hear, ye deaf; and look ye blind, that ye may see.
19. Who is blind, but my servant? Or deaf; as my messenger that I sent? Who is blind as he that is perfect and blind as the Lord's servant?
20. Seeing many things, but thou observest not; opening the ear's, but he heareth not."

Isaiah 53:1-2
"1. Who hath believed our report? And to whom is the arm of the Lord revealed?
2. For he shall grow up before him as a tender plant, and as a root out of a dry ground: he hath neither form nor comeliness; and when we should see him, there is no beauty that we should desire him."

In the above quotes the "Lord's servant", the "messenger" and the "arm of the Lord" are all names for one thing, *Amanita muscaria*. The Lord's servant is "blind" "deaf" and "perfect" and who opens the eyes of the blind and the ears of the deaf. The arm of the Lord is described as a "tender plant", as a "root" out of dry ground, and that when "seen" is not a thing of great beauty.

Many modern Christians claim that Isaiah 53 is a prophecy or vision of Jesus and the crucifixion. I believe that Isaiah 53 is not a vision or a prophecy of any kind, but is simply the words spoken in the ritual as the Soma plant was processed into the Soma drink in Isaiah's version of the Soma ceremony.

21. New Testament Bible Quotes

The New Testament Bible is perhaps the most misunderstood and misinterpreted book ever written, with dedicated Christian scholars and those who hate the book and Christianity both being completely ignorant of what this book is really about i.e. Soma.

What sets this collection of books apart from other ancient texts on the Plant God Soma and has caused this confusion; is the extensive personification of the Soma Plant as the hero "Christ Jesus" of a story that was written as being a real historical event.

The quotes were chosen to show that the Christ was to be "tasted", "eaten" and dates "from the beginning" all things that are impossible for a man. The words in bold print are supposedly those words straight from the mouth of Jesus as the founder of Christianity.

Milk of the Word
Taste the Lord
Living Stone

1 Peter 2: 2-4
2. As newborn babes, desire the sincere milk of the word, that ye may grow thereby:

3. If so be ye have tasted that the Lord is gracious.
4. To whom coming, as unto a living stone, disallowed indeed of men, but chosen of God, and precious.

Tasting the Heavenly gift
Hebrews 6: 4-5
4. For it is impossible for those who were once enlightened, and have tasted of the heavenly gift, and were made partakers of the Holy Ghost.
5. And have tasted the good word of God, and the powers of the world to come.

Living Water
Gospel of John 7:37, 38
"37 In the last day, that great day of the feast, Jesus stood and cried, saying, If any man thirst, let him come unto me, and drink."

"38 He that believeth on me, as the scripture hath said, out of his belly shall flow rivers of living water."

Amanita muscaria is a most unique drug plant that when consumed in quantity produces potent psychoactive urine.

Bread of Life
Gospel of John 6:48-58
"48. I am that bread of life.
49. Your fathers did eat manna in the wilderness, and are dead.
50. This is the bread which cometh down from heaven, that a man may eat thereof, and not die
51. I am the living bread, which came down from heaven: if any man eat of this bread, he shall live for ever: and the bread that I will give is my flesh, which I will give for the life of the world.
52. The Jews therefore strove among themselves, saying, how can this man give us his flesh to eat?" (This is a very good question, an obvious hint to the wise that no man is speaking, and an excellent distraction to the unwary by maintaining the illusion of reality being narrated.)
53. "Then Jesus said unto them, Verily, verily, I say unto you, Except ye eat the flesh of the Son of man, and drink his blood, ye have no life in you.
54. Whoso eateth my flesh, and drinketh my blood, hath eternal life: and I will raise him up at the last day.
55. For my flesh is meat indeed, and my blood is drink indeed.
56. He that eateth my flesh, and drinketh my blood, dwelleth in me, and I in him.
57. As the living Father hath sent me, and I live by the Father: so he that eateth me, even he shall live by me."
"58. This is that bread which came down from heaven: not as your fathers did eat manna, and are dead: he that eateth of this bread shall live forever."

Word of God
Gospel of John 1:1-4, 14
"1. In the beginning was the Word, and the Word was with God, and the Word was God.

2. The same was in the beginning with God.
3. All things were made by him; and without him was not any thing made that was made.
4. In him was life; and the life was the light of men.
14. And the Word was made flesh and dwelt among us (and we beheld his glory, the glory as of the only begotten of the Father) full of grace and truth."

Now, compare to the Rig-Veda speaking of Soma:

R.V. 1X87 2cd "Father of the gods, progenitor of the moving force, mainstay of the sky, foundation of the earth."

R.V. 1X76 4 "Monarch of everything that sees the sun light, Soma cleanses himself, triumphing over the Prophets, he made the Word of the Way to resound, he who is cleansed by the suns ray, he the father of poems, master-poet yet equaled."

The Word of the New Testament cannot be fitted to a man, no matter how you twist logic and belief. It does, however, fit perfectly with the Rig Veda's eloquent Word of the Way, the father of the Gods, the Master-Poet, without any problems.

Son of God
John 3:16-17
The most "quoted" line in all of the New Testament writings is John 3:16.
16. "For God so loved the world, that he gave his only begotten Son, that whosoever believeth in him, should not perish, but have everlasting life.
17. For God sent not his Son into the world to condemn the world; but that the world through him might be saved."

A "man," or the real Son of God; *Amanita muscaria*, the herb of immortality, the whole conception of Christianity is completely changed by which viewpoint is used "Man" has a God who demands the human sacrifice of a perfect man, to make up for human disobedience (free will), no loving God here.

"Herb of Life", the sky father sends his son (*Amanita muscaria*) nature's greatest gift to man. A loving, caring God, a father that gives, not demands. The son brings his gifts to humanity, Wisdom, prophecy, joy, new life, health, love, immortality and who even when sacrificed lives again.

Word of Life
1 John 1:1-2
"1. That which was from the beginning, which we have heard, which we have seen with our eyes, which we have looked upon, and our hands have handled of the Word of life;
2. (For the life was manifested, and we have seen it, and bear witness, and show unto you that eternal life, which was with the Father, and was manifested unto us.)"

This simply can't apply to a "man" by any stretch of the imagination. It does, however, make a perfect fit with the herb of Immortality. The New Testament's Word of Life is composed of two Rig Veda terms for the Soma, Word of the Way and the Herb of Life. Substitute herb of life; for Word of life and you have a perfectly logical statement. In the herb cult context it is perfectly logical as written.

Who is the Christ?
Mathew 22: 41-46
"41. While the Pharisees were gathered together, Jesus asked them.
42. Saying, What think you of the Christ? Whose son is he? They say unto him, the son of David.
43. He saith unto them, how, then does David in spirit call him Lord, saying.
44. The Lord said to my Lord, sit thou on my right hand, till I make thine enemies thy footstool?
45. If David then calls him Lord, how is he his son?
46. And no man was able to answer him a word, neither did any man from that day forth ask him any more questions."

I had to read this statement several times to really understand this most profound question in line 45. The statement in line 44 quoted from Psalm 110.1, is written from the perspective of the scribe, or in the third person so it is saying the Lord (the God) said to my (the Scribes) Lord (King David).

Here we have "Jesus," plainly stating through the use of a clever question; that no son of David; himself included, could ever be the Christ. Now this statement from the founder of Christianity completely contradicts the belief of all Christian Churches that state "Jesus the son of David is the Christ".

The phrase "in spirit" is the New Testament's way of saying intoxicated on Soma. It was common in the Persian Soma usage to have a scribe present whenever a Magi or Prince consumed the Soma, to record every word of that person's conversation with the God Soma or to record other impressions of the person's experience, this recording of the interaction between a man and the "living" God is the root of the ancient practice of prophecy.

Many Christians would be surprised to know that the late Roman emperors manufactured the Religion now called Christianity, in a desperate attempt to hold a crumbling empire together. Elements from several different religions were combined to create a "universal" or Catholic Church, which was established to stabilize and unify the Roman Empire.

Zoroastrianism, Mithraism, the cult of Dionysus, the cult of Isis and Osiris, the cult of Amen and many others, were all used to create Christianity. All of these ancient religions were widespread thru out the late Roman Empire and are still detectable in modern Christianity, the cult of Isis has become the cult of the Virgin Mary, Mithras/Osiris/Dionysus combined have become the Christ, and every Christian knows that hymns and prayers end with "Amen" the name of the ancient Egyptian god Amen. The New Testament texts that Christianity is based on were extensively edited for content, and even rewritten by people employed by the Roman Emperors to create this new religion. Many texts that did not fit into this new scheme were simply dropped from the list of acceptable texts, and in some cases were banned outright.

This Frankenstein's monster creation of the Roman Empire has carried on a war for almost 17 centuries trying to subjugate or eradicate all other belief systems in an effort to become the "Universal" church of the world. They have warred upon heretics, scientists, witches, pagans, people of other religions, and splinter sects of their own religion. This cult of human sacrifice masquerading as a religion is in reality a political machine designed for world conquest.

While I value the New Testament texts as one source of information on the Soma God, I have absolutely no use for the "Christian religion" as currently practiced.

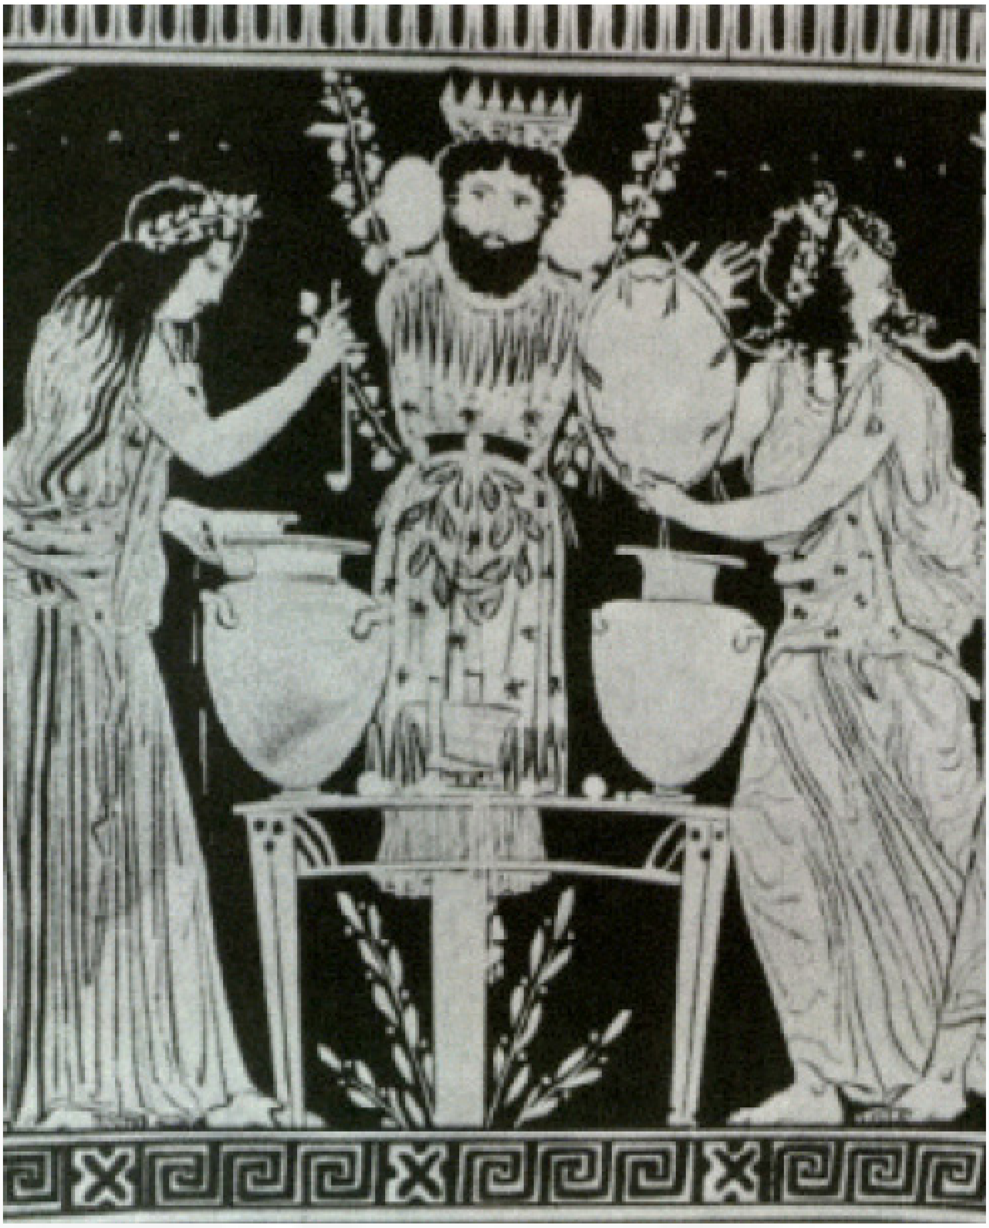
22. Dionysus

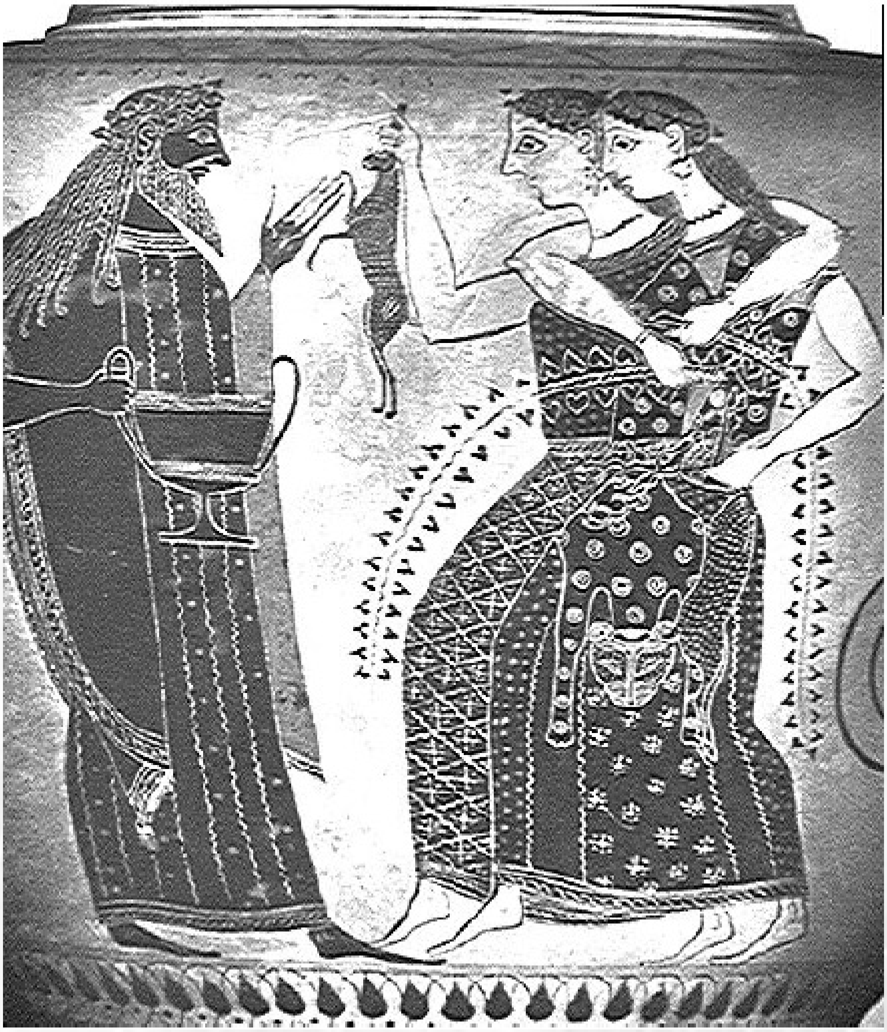


Dionysus as a white pillar receiving offerings, note small white mushroom shaped objects on table.

All ancient Indo-European peoples possessed variants of the Soma Ceremony; the Greek god Dionysus is an example of a Greek variant of the ancient Soma God. Dionysus is an extremely old God whose name was found on a fired clay tablet written in Linear B script, an archaic form of Greek that is pre alphabet and dates to about 1450 BC.

Dionysus caused vines to spring up over night bearing Wine; obviously this is no grape vine. His Priests could convert fresh grape juice into a special potent wine over night and any cup this Wine was poured into became a Sacred object ie. A Holy Grail.

His female followers went into the woods in a sacred hunt for the God himself who was in the form of "little spotted animals" who later were torn to pieces by the women with their bare hands.

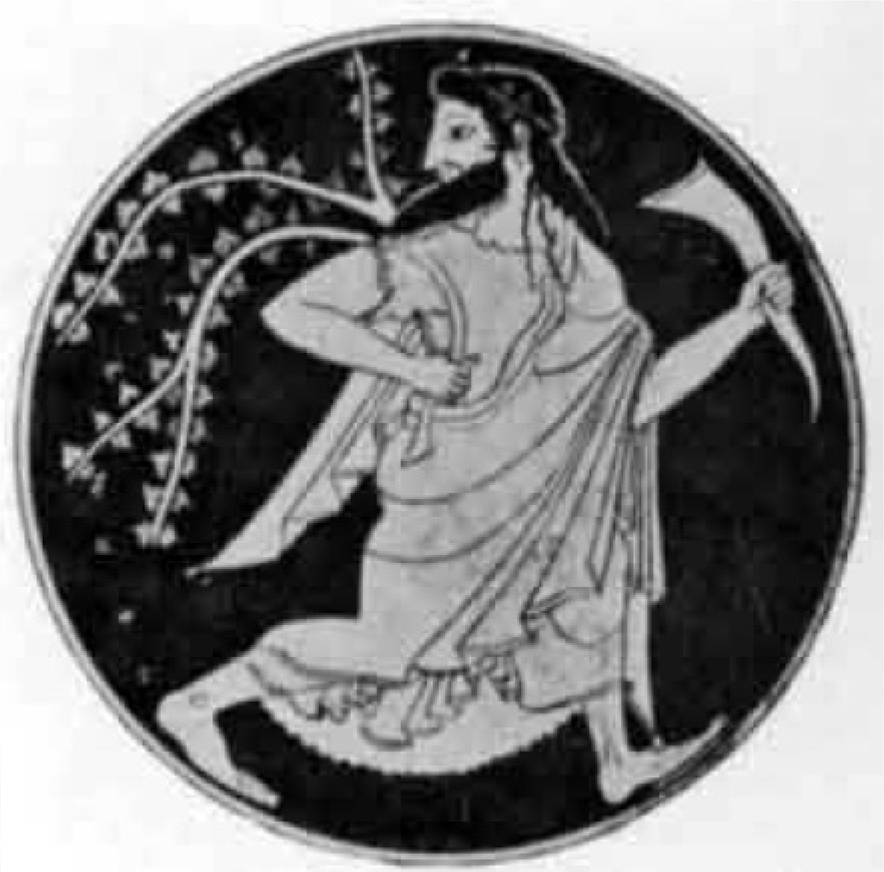


Dionysus receiving small spotted animals from his female followers.

The cult of Dionysus was very secretive with only woman worshipers and his male priests being admitted to the secret nighttime services. In many cases all males were excluded from certain temples or ceremonies. The cult of Dionysus also had a very public face with mass public drinking of the cults Wine at special festivals and entertainment with plays, poetry, song and theater.

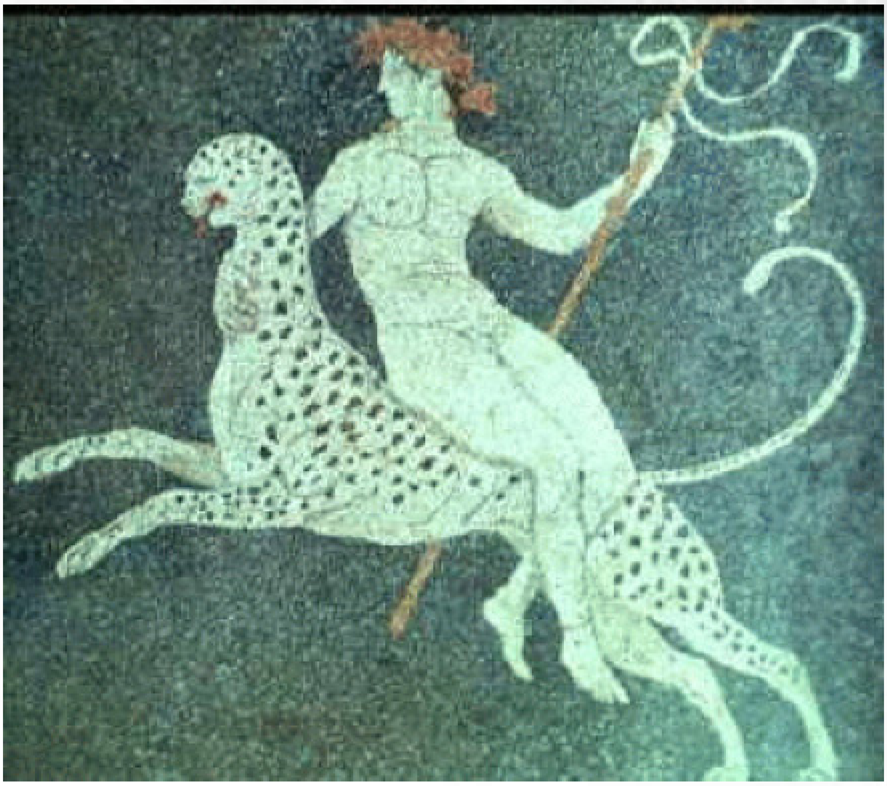
When this cult reached Rome in about 300 BC it was soon outlawed and by the Romans own count more than twenty thousand people were crucified, the majority women, the Romans replaced this secretive Dionysus cult with their public cult of Bacchus and these two Gods have been confused with each other ever since.

The true cult of Dionysus survived being outlawed losing the wild ecstatic dancing that marked its earlier form and eventually evolving into a religion of personal salvation, until it was outlawed by the Roman Catholic Church as being a Pagan religion.



Above; Dionysus with "Grape vines" sprouting from his back, carrying his magic drinking Horn or Cornucopia.

Below; Dionysus riding a Leopard.



23. Odin; God of Wisdom

The Germanic and Nordic, "Wotan", "Woden" or "Odin" the premier God of the North; a god of war, wisdom and secret knowledge, who possessed the poetic mead of inspiration.

Odin is only one of two to three hundred names for this God, these including Ygg = egg, Jalk (English Jack) = youth, Sidhot = slouchy hat, and Sidskeg = the long beard. These names are a precise fit with the visible *Amanita muscaria* Life cycle, which starts with an egg, growing into a youth, maturing into a slouchy hat, and finally into the long beard "mycelium".

Odin has only one eye, he gave up the other one as payment to drink from the well of knowledge, if you pick a fresh *Amanita muscaria*, remove the cap from the stem and look at the underside of the cap you will see what looks like a single giant eye.

Odin pierced by his own spear, hung himself on the world tree for nine days and nights distilling wisdom, fresh *Amanita muscaria* must be dried before consumption, anciently it was threaded onto a string and hung up to dry, it having no wisdom or knowledge in it when it's fresh.

Many of the Myths of Odin concern his attaining the Poetic Mead, the most precious drink in the universe; it was stored in three casks the Red, the Gold, the Brown, which are the three most common color phases of *Amanita muscaria*. One Myth says Odin has a magic Goat that every day fills a pitcher with the poetic mead, the magic goat (mycelium) and the never-ending pitcher of Mead are just another version of the Holy Grail myth.

A separate Norse Myth concerns the "Golden Apples of Immortality", which all the Germanic Gods had to consume daily to stay young and strong.

Most of the myths of Odin are found in the Elder Edda; which is a collection of the ancient Norse/German mythology saved from oblivion in the late middle ages. The similarity between the words Veda and Edda is no coincidence according to the Indo-European language experts, which believe they both descend from a common ancestral Proto-Indo-European word for Wisdom/Knowledge thus the Elder Edda means the Old Wisdom/Knowledge.

Christianity replaced the old German religion in Scandinavia only 1000 to 800 years ago and like it did everywhere it gained political control, it suppressed the Old Knowledge with persecution of all the remaining followers.

In response some of the Old Wisdom religion found it's way into childhood stories like Jack and the beanstalk and of course there is Odin playing Santa Claus.

Jack and the Beanstalk

The Jack stories are very popular childhood entertainment throughout the Germanic world including England. As with all folklore, there are several different Jack stories and of course local varieties of the same story. The English name "Jack" or the Norse "Jalk" means a "Youth" and is one of the old names of Odin.

In the Jack the Giant killer stories Jack does exactly the same thing Odin does in his ancient stories namely overcome Giants, with only the name of the hero God changed to protect the storyteller from persecution. In Norse mythology things are not as they are said to be, in fact they are always named as an opposite, for example a giant in Norse Myth is not really a giant but a man. Once you understand that Odin is *Amanita muscaria* and men are giants compared to him, his stories of "slaying Giants" is easy to understand and probably warded off the uninitiated person from even touching Odin the Giant killer

In the Jack and the Beanstalk story, Jack trades a cow to an old man for three "magic" beans; the code breaker is the word magic or Maga which is one of the oldest names for *Amanita muscaria*, in the Rig Veda the going rate for Soma is three Somas for one cow, so Jack didn't get ripped off he just paid the going rate.

The magic beans in the story sprout into a gigantic beanstalk that reaches to heaven. In reality Jack would consume these three Maga and have visions, the theme of climbing the World Tree is common in Nordic Shamanism and by climbing up into heaven, or down to its roots in the underworld the Shaman's spirit could visit all the regions of existence.

At the top of the beanstalk/world tree Jack discovers a Giant that wants to eat him, a bag of "Gold" that never runs out, a Golden Harp that recites poetry, and makes music by itself, and the Goose that lays Golden Eggs.

The never-ending bag of Gold recalls the Bhagas of the Rig Veda, the leather bags used to carry the dried Soma plants to the Soma ceremony, these bags gave the name Brahmans or "bag-man" to the ancient Soma drinkers. Now if you know where the Somas grow, your bag will never be empty, plus at three Somas per cow this knowledge could generate real wealth.

One of the most surprising effects of consuming dried *Amanita muscaria* are the auditory effects, these can be very beautiful poetry, music or the spoken word. There is simply no comparison to real music as the auditory effects can be orders of magnitude better than ordinary music. Thus, the stories "golden harp" that sings and plays it's own music.

The Golden Eggs supposedly produced by a "goose" are obviously *Amanita muscaria* mushrooms, which when just emerging really are small golden eggs. In the Rig Veda Soma is called the Golden Embryo the most precious thing in all creation, while one of Odin's names is Ygg, in English egg.

Santa Claus and Christmas

In Siberian folklore, reindeer, which love eating *Amanita muscaria* and becoming intoxicated, are always associated with the mushroom. In the Santa story the reindeer not only pull a sled, but can also fly into the sky. This symbolism should be obvious, since people who have eaten dried *Amanita muscaria* often report flying as one of the visions, such people would of course think a stoned out reindeer was also capable of this kind of shamanic "flying".

Santa; the jolly little fat guy, with a long white beard, in a red and white suit, who can travel around the world in a single night leaving brightly wrapped "presents" under evergreen trees is obviously *Amanita muscaria* personified.

Amanita muscaria is little in size yet quite fat, full of laughter and joy when dried and consumed, it produces a long white mycelium when resurrected that resembles a white beard, it is the only brilliantly red and white life form in the northern forest, it can come up over a very large area in a single night, it is a symbiot with evergreen trees like Pine, Fir, and Spruce, and is obviously the brightly wrapped presents to be found under these trees. The Santa story is Norse/Germanic in origin, and the earliest known German Christmas tree ornaments are painted wood or glazed ceramic *Amanita muscaria* representations.

This Santa story appears to be shifted six months on the Solar calendar, probably to avoid the church's persecutions and to bring it into line with the Church's calendar. Since, in the far north *Amanita muscaria* fruits during or after the longest days of the year. While the modern Christmas or (Mithra's birthday) is celebrated during the shortest days of the year, when *Amanita muscaria* fruits in the much warmer Mediterranean basin area.

However, the ceremonial sharing of dried *Amanita muscaria* at a midwinter celebration in the northern forests may be an ancient practice since the antibiotics it contains and it's light increasing mood-enhancing intoxication would probably be most needed by the ancient peoples at this bleak time of the year.

24. Amanita muscaria and Philosophical Alchemy, Hermeticism, the Occult and Judeo-Christian Mysticism

Each of these categories are often considered to be separate belief systems and yet these belief systems are mixed to such a large extent that there is no "pure"strain. Alchemy for example contains elements of Hermeticism, Occultism, and Judeo-Christian mysticism, and each of these categories also contain major elements of the others.

These belief systems were developed or surfaced during the early Medieval period under the fierce persecution of heretics and other thought criminals by the Roman Catholic Church, thus many of their texts are written in a way the church would not suspect of heresy and often symbols and pictures are used instead of words to carry meaning in the form of a symbolic language.

In a further effort to keep their heads upon their shoulders many authors of these texts used assumed names and since Europe's Jewish population was not subject to the same rules the church applied to Christians, many "Christian"authors used Jewish names. However there is considerable cross over between Christian, Muslim and Jewish thought at this time and the Kabbala was widely studied by Alchemists and Hermetic students. The use of assumed names by authors of these types of texts lasts until the 1600"s when the power of the Church to torture and kill for the crime of heresy declines in most areas of Europe, only then authors began to put their own names proudly on their work.

Alchemy is the art of transmutation, which is divided into the two main branches of Practical Alchemy and Philosophical Alchemy. Practical Alchemy concerned itself with the transmutation of lead into gold and the experimental exploration of matter which over time developed into the science of modern chemistry, this branch of Alchemy does not concern us, except to realize that not all Alchemy is the same.

In contrast the goal of Philosophical Alchemy is the spiritual transmutation of men into more than man through the use of the Philosophers Stone and the Elixir of Immortality. These Philosophical Alchemy texts are full of bizarre imagery and veiled references to *Amanita muscaria* as the Philosophers Stone the source of the Elixir of Immortality. They also show a series of transformations involving the Philosophers Stone which when understood as *Amanita muscaria* corresponds with the resurrection of the dried mushroom and the secret of the Holy Grail.

Hermeticism is a mixture of beliefs drawn from Egyptian and pre Christian Greek sources. The Egyptian god Thoth was thought to be the author of several Hermetic texts. The Greek name for Thoth is Hermes Trismegistus meaning "Hermes the thrice greatest". Many Hermetic authors signed their work as Hermes Trismegistus or variations thereof believing the text was directly inspired by Hermes Trismegistus. The Greek god Hermes (Roman Mercury) is found widely in Hermeticism, Hermes is winged with wings on his ankles, shoulders, or on his head and he carries the same winged staff wound with serpents, "the caduceus' that modern Medicine uses for it's symbol of healing. The Greek Hermes, a healer, the god of commerce, invention, cunning, theft, messenger and herald to the other gods, a patron of travelers, and leader of souls to the underworld. Hermes is also associated with Hermaphroditism (Hermes + Aphrodite) the occurrence of male and female sexual characteristics in the same body, named after Hermaphroditus the son of Hermes and Aphrodite, who became united in one body with the female nymph Salmacis. This joining of the opposites of male and female in one body is apparent in the *Amanita muscaria* mushroom which appears to be both male and female genitalia. Hermetic also stands for sealed, a Hermetic seal is air tight thus Hermetic knowledge is Sealed knowledge, one must break the code to access the sealed knowledge.

Occult means hidden, as in hidden knowledge, the occult is often thought of as dealing with "supernatural" knowledge, and viewed from the standards of the Church as being evil, even Satanic. Yet, the Occult is best understood as Esoteric knowledge that was intended for only a few people. Esoteric and Occult are synonyms for the words mystery and mysterious which evolved from the Mystery religions of ancient Eurasia.

From the ancient Mystery religions we also have Mystic and Mysticism. Followers of Mysticism are often outward believers in more organized religions and are often called Christian mystics or Jewish mystics yet all Mystics share more in common than their religions seem to share. All branches of mysticism believe in the personal experience of God through a divine rapture, an indescribable bliss which carries them to other levels of perception and reality. The belief that man in a physical body can experience God seemed heresy in the more organized religions and Christianity, Judaism, and Islam have all persecuted Mystic sects.

Not all Mystic sects know of *Amanita muscaria* and some would not use it if they knew that secret, instead the rapture is generated through meditation or other means, including other psychoactive drugs such as Hashish used by some Hindu and Muslim mystics.

There is however a large number of Christian and Jewish Mystics that did know of and use *Amanita muscaria* as a Sacrament. Some like Jacob Boehme created beautiful images containing the *Amanita muscaria* Sacrament in plain sight. Hiding the Secret in images that can only be understood if you already know the Secret, is one way to preserve and pass on the Sacred knowledge. Only those with eyes to see will see.

25. Some Thoughts

Amanita muscaria is the most widely distributed natural intoxicant on planet Earth being found on all continents except Antarctica, this fact in itself would guaranty a lot of stories about *Amanita muscaria* worldwide. *Amanita muscaria* when properly prepared is a much safer plant intoxicant than many commonly used intoxicating plants like poppy, henbane, datura, or belladonna since these plants can easily cause death with just a small overdose.

In the northern forests *Amanita muscaria* is the most easily recognized and exploitable source of large quantities of effective antibiotics, this would also generate a lot of stories of *Amanita muscaria* doing miraculous healing and cures.

The *Amanita muscaria* mushroom is very distinctive in appearance and with a little training is easily distinguished from all other mushrooms, some of which can be deadly.

The Immortality exhibited by *Amanita muscaria* is a source of wonder, and the source of all the magic vessel legends of ancient Eurasia. Since this immortality can be exploited by using magic cups or other cultivation techniques to extend the supply of this very special life form the cults using *Amanita muscaria* would not have to maintain a large supply of mushrooms.

The unique fragrance and taste of dried *Amanita muscaria* resembles honey and is sweet to the taste unlike most other medicinal or psychoactive plants.

Our ancestors discovered a living treasure in the forests and they used it. This practical knowledge they passed from generation to generation for ages in story, song and ritual.

Some time between the ancient world and the modern world the secret to understanding these stories and rituals was lost. These stories evolving into sacred books, myth, or Folk stories while the rituals became the outward signs of various religions, yet without the knowledge of the ancient sacrament the stories became unintelligible and the ancient rituals became meaningless.

The real and practical ancient living god of our ancestors was hidden from us and was replaced by a truly worthless even dangerous supernatural god. This is a concept of god created by men to control men, as this modern god is really an anti-god, whose followers have killed millions through warfare, persecution and ignorance. This invisible modern god cannot fulfill the ancient promises of the real "Living God"; since it is a god who opens not the eyes of the blind, that leaves the sick diseased and the lame crippled.

For the true seeker, know that in the real world, you can find a real forest that is home to the ancient living god of our fathers. The ancient Garden of paradise has always been here; in this earthly garden is the Fruit of the Tree of Wisdom and Life. Taste for yourself nature's honey sweet medicine, heal your body and spirit, let your eyes be opened and become reborn as gods. This is the promise of the ancient Knowledge; this is your ancestral birthright.

26. The Names of a God, Part 1

What's in a name? Everything! The ancient Indo-Europeans and their descendants attached a lot of meaning to names, yet names, no matter how long, can convey only so much meaning. Where there is a mystery full of meaning to try and convey, as in the herb of Life, one name simply cannot do the job. In the case of *Amanita muscaria*, the names multiply giving it more names than any other life form. Most of the names are attributes or descriptions of its effects rather than physical descriptions, but these also exist in abundance. Since we are dealing with a physical plant that has many mental and physical effects on the human body, the multitude of names makes perfect sense.

In contrast, the truly supernatural gods have very few names. Zeus is basically Zeus, while Yahweh, his Hebrew counterpart, is always Yahweh. Yahweh's messenger, the Messiah, however, has over 50 names in the Old and New Testaments.

Many of the names have to do with one effect, the production of auditory effects. A dead dry plant, with no lips or tongue, speaks, leading to names such as The Messiah (messenger), the Word, the Word of the Way, the Tongue of the Way, the Word of God, etc., etc. These names causing endless confusion for scholars who don't know a plant can speak!

Many other names are based on the fact that *Amanita muscaria* is "Immortal" in the truest sense of that word. This has also caused endless confusion for scholars who do not understand that *Amanita muscaria* is truly immortal, in the literal sense of the word.

Other names are, of course, based on other effects. In this section, we will take a closer look at some of these names of god. Names will be drawn from many sources, Ancient Aryan, Greek, Persian, Hebrew and Christian. The abbreviations are R.V. = Rig Veda, Ys = Yasna, O.T. = Old Testament, N.T. = New Testament.

Greek - Ambrose,
R.V. - Amrita,
"Not mortal". Seems to refer to both plant and juice extracted from the *Amanita muscaria* after it has been dried then rehydrated with water. In the Greek legends Ambrose is sometimes called Nek-Tar (see Nek-tar).

R.V. - Andhas,
"The Flower" The ancient Aryans sometimes referred to Soma as "the flower" dried *Amanita muscaria* has a very pleasant aroma, the association of flowers and nectar probably arose from this plant, which is both the flower and the nectar.

O.T., N.T. - Be-el-ze-bub
"The lord of the flies" or "God of the flies"; this name has been demonized extensively; however in its original plain meaning it is very descriptive of the herb, since living *Amanita muscaria* is often surrounded with clouds of small flies or gnats while larger flies may be found sitting on it, or laying under it, completely comatose. Dried *Amanita muscaria* in milk is irresistible to flies, the flies becoming very intoxicated. The modern common name, fly Agaric, and the scientific name, *Amanita muscaria*, associate this mushroom with a power over flies.

There are 7 references in the New Testament to the "Lord of Flies" (Beelzebub) and all of these are associated with "Jesus", they are Matthew 10:25, 12:24, 12:27, Mark 3:22, and Luke 11:15, 11: 18, 11:19.

R.V. - Born of Thunder
The *Amanita muscaria* mushroom, having no visible seeds or root system anciently was thought to just spring up with the sound of thunder. In effect an Immaculate Conception for an herb full of wonder and divinity. This concept leads to the Son of God, Son of Zeus, and Son of the Sky Father names.

R.V. - Comforter
O.T. - Comforter
N.T. - Comforter
As the "comforter," the herb is held in the highest esteem by these three variants of the ancient religion. The New Testament has the most references to the comforter as the Holy Spirit. The "Holy Spirit" is a description of the herb's effects after ingestion.

O.T. - Counselor
R.V. - Counselor
As the advisor of the seers (prophets) who then advised other men, the counsel of the herb was considered to be the highest available to mankind.

Greek - Dionysus
"The Son of the Deity." The cult of Dionysus shows obvious signs of being originally a cult of the herb, such as the vines yielding wine that appear overnight, with the emphasis on intoxication. The ritual importance of small spotted "animals", and the sacred hunt in the woods for these spotted creatures (*Amanita muscaria*), plus the fact that women were supposed to tear these "animals" (Dionysus himself) apart with their bare hands. Dionysus is personified as the sacrificial victim in this ritual. Dionysus as depicted sometimes, wears a scarlet mask and a leopard skin. Behind his mask he's hiding a secret, his inner self. The most common cult object was a white post with the scarlet mask hanging on top, phallic or fungus? The cult's main objective was

to induce a divine ecstasy in the Maenads (female worshipers).

R.V. - The Father of the Gods
Ys - The first and last
O.T. - The first and last
N.T. - Alpha and Omega
The idea that this plant was and should be considered the beginning of western religion is anciently held to be true. As the father of the gods, the Soma was thought to have produced the gods and they the universe, the Soma plant, being a god, high priest and sacrifice in the Soma ceremony. Obviously in the visions and auditory effects induced by this plant, we find the birthplace of the gods and religion.

R.V. - A fountain made of gold, the fount
O.T. - The fountain of living water
N.T. - The fountain of the water of life
"The fountain of living water" is closely associated with the idea of amrita, ambrosia, the elixir of immortality. The body of the herb that provides this amrita appearing like a small spring of water that eventually shoots up into a frozen fountain shape, bearing in this form, the water of life, it had mysteriously brought up out of the earth.

The large bowl holding the Soma juice is called the fount in the Rig-Veda, the ancestor of the fount of holy water in Christian churches. R.V. 9 XCVII 44, "Pour us a fount of meath, a spring of treasure." In the Rig-Veda the water extraction and filtering process is poetically compared with oceans, rivers, streams, fountains, springs and drops of rain.

Greek - The Golden Apples of Immortality
Latin - The Golden Apples of Immortality
Norse - The Golden Apples of Immortality
Greek, Roman and Norse mythologies all mention the "golden apples of immortality" in several legends. In Greek and Latin, the word for apple is also used in a generic sense for fruit. Button stage, *Amanita muscaria* specimens, when dried whole, definitely resembles small golden apples. These golden apples are the most precious things mentioned in these myths as the immortality of the gods themselves depended on them.

N.T. - The living bread
These names of the Christ, as being the living bread, the bread of life and the bread from heaven all point to the consumption of "*Amanita muscaria*" as heavenly food. All three have correspondences such as:

N.T. - the living God
N.T. - bread of life
N.T. - living bread, living stone
N.T. - bread from heaven
The food of Gods -R.V.
Chief of all foods -R.V.

Lord of Life - RV
Deathless God - RV
The *Amanita muscaria* mushroom certainly is a living being, it is also the only plant in all of human history to be considered a God! The psychedelic mushrooms used by the Mexican Indians are considered messengers, not god.

N.T. - a living stone
A fairly good description of living *Amanita muscaria*, in the young growth stages, this living stone is the foundation of Christianity. That people either accepted it or were offended by it is plainly written, (see I Peter 2:4-8).

R.V. - Madhu
"Honey, Sweet". The Soma is called honey more often in the Rig Veda than any other single description. The juice of the dry *Amanita muscaria* after rehydration with water is very sweet to the taste, in contrast to other available drug plants such as *Datura*, Henbane, Opium and Ephedra. These have a bitter or nasty taste; none

of these could be called sweet. (Ephedra is one of the modern substitutes used by Hindu Brahmins in today's Soma ceremonies and in the modern Zoroastrianism Haoma ceremony, leading many to believe that it is the original Soma/Haoma. Ephedra contains Ephedrine an Amphetamine, which produces exhilaration and some euphoria, but it does not produce the original Soma's effects of visions, auditory effects, rapturous intoxication or psychoactive urine.)

R.V. - Master Poet or The Lord of Speech, Sacred Bard (Poet)
A speaking name for Soma in the Rig-Veda, Soma being the father of poems, a master poet never yet equaled! The auditory effects again being stressed in the highest terms. The Soma is the inspiration of poets and prophets.

O.T. - The Messiah
N.T. - The Christ
"The Messenger." No other name has caused as much confusion as this one. This is a speaking name, like the Word of the Way. Because of this, the messiah is thought to be a man by the uninformed. That the messiah of the Old Testament prophets could not be a "man" is plainly evident in their description of god's messenger.
Isaiah 42:19-20
"19. Who is blind, but my servant? Or deaf, as my messenger that I sent? Who is blind as he that is perfect and blind as the Lord's servant?
20. Seeing many things, but thou observest not; opening the ear's, but he heareth not."
Isaiah 53:2
"2. For he shall grow up before him as a tender plant, and as a root out of a dry ground."

The messiah is blind, lacking eyes, deaf, lacking ears, but he opens the eyes of the blind, and opens the ears of men, both are effects of the herb of Life. The description as a tender plant is botanically correct, since few plants are as "tender" as the living *Amanita muscaria*; which in arid areas sometimes fruits in ground as hard as concrete, I have personally observed this in Arizona, U.S.A.

The Old Testament prophets simply pounded this plant after rehydration with water to yield its juice, exactly the same as in the Soma and Haoma ceremonies. Isaiah Chapter 53 is, I believe, the liturgy spoken as this processing went on. The linking of this plant with prophecy extends thousands of years prior to Isaiah's time. The wonder of a dry dead plant, speaking, would raise its messages to the highest levels in the eyes of the ancient peoples. The fact that some of what it said sometimes came true raised it even higher.

R.V. - Nek-tar
Greek - Nectar
Nek = Corpse + Tar = overcomer
The "corpse/death overcomer." An ancient word based on the herb's resurrecting ability, giving it a central place in the ancient Aryan religion, as the bringer of immortality to mankind. The gods of the Greeks drank Ambrosia, the Nectar that made them immortal.

The possibility that regular, ritual consumption of a plant, exhibiting antibiotic antiviral properties, that may extend the span of human life, should be thoroughly investigated. There must be some logic to this extremely ancient and long running belief.

It is interesting to note that Soma drinkers in the Rig Veda were expecting 100 years as a lifespan, with the possibility of many more. In contrast to the bible's three score and ten (70 years) with the possibility of another decade or two. The only Biblical exceptions were the prophets who were also herb users with many of them living well past 100 years.

O.T. - Prince of Peace
I believe this name is based on the calming effect caused by consuming dried *Amanita muscaria*. This inner peace is unique to this herb, it is thoroughly calming and yet clear, with almost no interference in thought or perception. It is the only mental effect produced by small doses (one to two grams of herb), the calming effect becoming more intense with stronger doses.

As an anti-anxiety agent, the ancients would have highly valued it. I believe their lives could have been much more stressful than modern existence. As a modern anti-anxiety agent it may find use, since compounds with similar effects are widely prescribed medications in modern society.

R.V. - Sage
It is hard for modern people to understand how a plant or the resulting beverage can be wise. But anciently, the herb was considered to be the source of wisdom, the creator of human sages.

As one who has tasted the herb, I have to agree completely with the ancients. Consuming dried *Amanita muscaria* creates extraordinary visions and auditory effects; these unleash a tremendous quantity of information. This is accompanied by lessons or teachings; the whole experience can be considered a learning experience, one that unfortunately, cannot be transmitted with words.

N.T. - Savior
O.T. - Savior - Redeemer - Intercessor
R.V. - Savitar or Savitr
The idea of the herb of Life being a savior, springs from the theology of the ancient Indo-Europeans where the supreme god(s) demands perfect justice in the judgment of the dead, all humans, of course, failing this judgment. The savior, however, intercedes for his devotees at the dead's judgment and, like a good lawyer, gets them off with all charges dropped. Savitar is a name for Soma in the Rig-Veda, and carries out the exact same function, as the savior in the Christian religion.

R.V. - Soma
Persian - Haoma
"The Pressed one" this name is based on the role this plant had in ancient Indo-European religion, where it was dried, then rehydrated with water and pressed or pounded to extract its juice. Soma can refer to the plant, its juice, the juice mixed with milk, the divine urine produced, or the god incarnate of the plant.

This plant god was the central sacrifice in the Soma ceremony. The purpose of this ceremony was to give the participants immortality. This ceremony is very ancient, being in existence before the invasions by the Indo-Europeans of Persia, Turkey, Egypt, India, Greece, Eastern Europe and Central China. From this ceremony, Hinduism, Zoroastrianism, Judaism, and Christianity are all descended.

O.T., N.T. - The Tree of Life
The Fruit of the Tree of Life
R.V. - The Tree
The Red colored Tree
The *Amanita muscaria*, as mentioned in the botany section, is a mycorhiza fungus. Being a symbiotic with certain tree species, pine, spruce, birch, fir, larch, and occasionally the oak, being the preferred species. All of the trees mentioned above have been considered trees of life by various Eurasian peoples.

The ancients obviously knew of the connection between the host tree and the appearance of *Amanita muscaria*, the true fruit of the tree of life.

O.T. - The Tree of Knowledge of Good and Evil
"The tree of knowledge" the legendary beginning of human awareness and thought in the Old Testament is attributed to the consumption of this plant by Adam and Eve, which opened their eyes and their minds. In this new self-awareness, they discover their nakedness and their humanity.

This Genesis story is obviously descended from older legends. The association of the herb of Life and serpent is found in many ancient legends where the serpent is the guardian of the herb of Life. Such as Indra slaying the monster serpent Vrtra to recover the cows (Somas) hidden in a mountain cave; or the epic of Gilgamesh, a Sumerian legend where Gilgamesh, after many hazards and adventures finds the herb of immortality (Molly) only to have it stolen back by the serpent when Gilgamesh falls asleep.

Later writers have obviously twisted the Genesis story of the tree of knowledge for religious control purposes. The greatest advance in human thought is represented as the fall of mankind, instead of being celebrated, it's condemned, how stupid!

N.T. - The Way
Ys - Asha - cosmic order, truth, justice
R.V. - RTA - cosmic order, eternal law
In the Rig Veda, Soma as the "Word of the Way" or "Speaker of Eternal Law" was believed to be the founder and upholder of the eternal law. This cosmic law was believed to permeate and order the entire universe. Establishing the movements and relationships of the heavenly bodies, the seasons, the gods, plants, animals, and man, Soma being the central sacrifice, in rites guaranteeing the continuance of this eternal law. On the individual level, consuming the herb was thought to bring the individual's morality into line with the cosmic order considered an essential ingredient in the spiritual rebirth experience.

R.V. - The Word of the Way
R.V. - Speaker of Eternal Law
R.V. - The Tongue of the Way
O.T. - The Word of God
N.T. - The Word, The Word of Life
In this series of names, we can plainly see the importance of the auditory effects produced by the dried *Amanita muscaria*. This concept, of the herb being the Word, is the foundation of these three variants of the old religion. That the ancients believed this herb, heaven sent to communicate with humans, was the word of god and spoke the truth is the basis of prophecy. The human prophet simply relaying the information the herb spoke. No other drug plant in Eurasia is known to consistently produce such auditory effects. The Siberian accounts of dried *Amanita muscaria* consumption by the natives, often mentions the auditory effects experienced by its users. See "Soma, Divine Mushroom of Immortality" by Wasson.

O.T. - Wonderful
R.V. - Wonder-worker
No other single item on this earth is as full of wonder as this plant. In the healing, prophesy, visions, rapture, other world journeys, its virgin birth, brilliant appearance, and resurrection; humanity encountered the amazing.

27. Names of a God, part 2

All the following names and descriptions were compiled from translations. Translations by their very nature cannot be exact. So when you compare these names to one another, it is the meaning, the concepts embodied in them that should be considered and compared.

Two translations were used for the Rig-Veda. The first is Wendy Doniger O'Flaherty's translations for "Soma, Divine Mushroom of Immortality" by R. Gordon Wasson ISBN 0-15-683800-1.

The second and much more complete translation is "Sacred Writings"; Vol. 5, "Hinduism the Rig Veda", translated by Ralph T. H. Griffith. A Book of the Month Club published by Motilal Banarisidas Publishers, PVT. LTD. Each one of these translations produced its own list of names for "Soma".

The names of "Haoma" were compiled from "The Gathas of Zarathushtra", translated by Piloo Nanavutty, published by Gantha Corp. 1999, ISBN 1-890206-09-1 Pub.

The Old and New Testament names of the "Messiah" were compiled from the "Holy Bible" authorized (King James) version, which, for all its faults and archaic English, is still one of the best translations into English, as far as accuracy goes.

Each name or description is referenced in the parent texts original style.

In The Sacred Secret, I did a comparison of the names of the Christ to the names of Soma and Hoama in a simple chart. I recommend every serious student should create your own comparison chart of names to prove to yourself that Soma, Hoama and the Christ can only be the same life form; and that life form is *Amanita muscaria*.

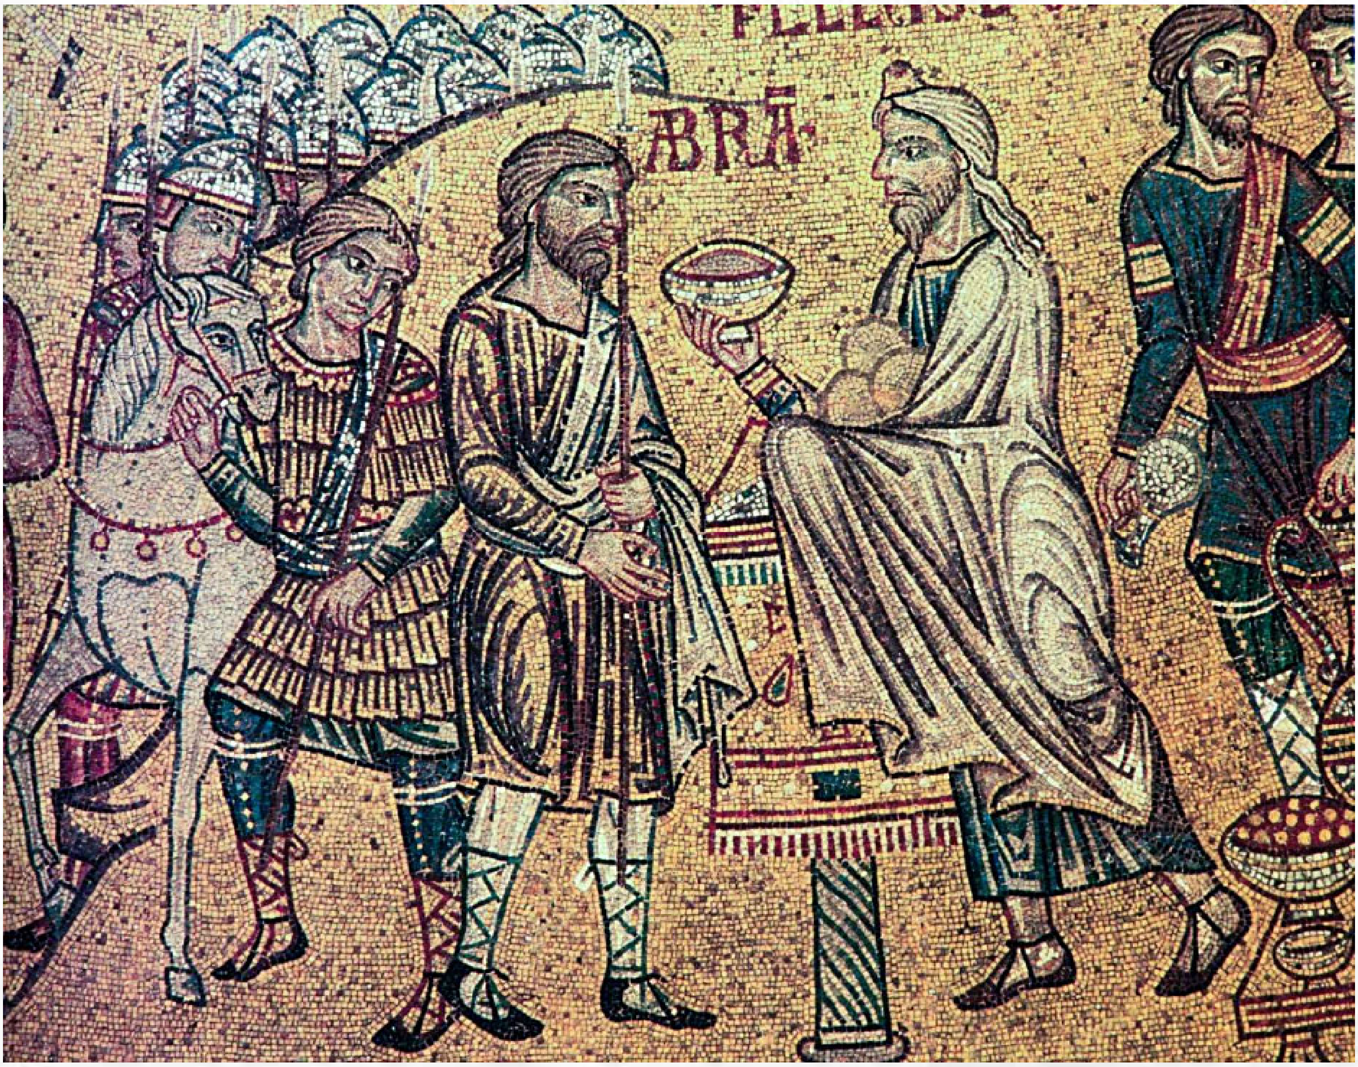
What was known to early Christians about the crucial Old Testament figurehead named Melchizedek was almost solely written into what would become known, after two long millennia since Jesus lived, as the Dead Sea Scrolls. So, his identity was either kept secret by initiated messianic Jews or by the later Church officials themselves. In Biblical canon, he was "the king of Salem and a priest of God Most High" during the time of Genesis (14:18), worshipful of the Israelite god El'Elyon ("God"). Scant detail was recorded in this canon about his lineage, his people, or any other authorities associated with him or under his command. In that he blessed Abraham, and Abraham paid him tithe, a divine right to rule was conferred to Abraham, whose descendants in as much were then made to respect Melchizedek as their Lord (Hebrews 7:8-11), who was "higher" than they and Abraham himself. What was to later Christians a taunting or sacred mystery regarding Melchizedek's lineage and Order, and in what way he was considered the Lord of Lords, or Most High Priest over the line of David (and therefore in their eyes the incarnate Lord over everyone), caused the Biblically exegetical Paul and Peter to regard him as immortal like God.

In that David wrote about a man becoming "a priest forever in the order of Melchizedek" (Psalm 110:1-7), the apostle Paul assumed that this person must have been of unique divinity - the most potent divinity - which he presumed could only be attributed to the Jesus he decried as having been God in flesh. This was a stance he took and wrote about (Hebrews 7:3, 7:8-11, 7:22-25) only after experiencing a peculiar hallucinatory blindness that caused him to see "a light from Heaven flashing around him" and hear instructions, from a voice claiming to be Jesus, to go to Damascus (Acts 9:3-6), wherein he was healed (an important account I discuss in following paragraphs). This would imply that the Psalm was a prophesy, in that David was Jesus' ancestor. However, Psalm 110 makes no mention of the anointed priest's name, his place in any lineage, or even if he was currently alive, a historical figure, or yet to be born (and therefore a prophesied figure). So, it is pure speculation that Jesus was the priest in the Psalm. None the less, due to Paul's freshly inspired and audacious fervor (Acts 22:14), and due to his influence as one who was converted to Christianity in the middle of his career as a key imperial Roman hunter of Christians, this Psalm went down in history as the most widely proclaimed testament to Jesus' immortality, a proclamation which was backed by Peter (Acts 2:32-35) and then affirmed by Clement I, the first Pope (ordained by Peter) and "fellow laborer" of the Apostle Paul [Atwill pp 38-39], to be the holy and infallible truth.

The true meaning behind the statement that Jesus had become "a priest forever in the order of Melchizedek," and therefore "immortal" like "God" (i.e., El'Elyon) - as Paul and Peter proclaim - would only have been known to those anointed priests in the Aaronic line serving David. This is realized by way of scriptural analysis of the Dead Sea Scrolls. In these texts, Melchizedek is a title meaning "Prince of Righteousness." This title is also used interchangeably with Michael, the "prince of light" (1QM 13:10-11; cf. 1QS 2:20-22; CD 5:17-19) and "the angel of [God's] truth" (1QS 3:24), highest of all of God's princes, implying that "Michael" (actually Micha'el) was either his first name or a moniker for his rank in the Order. The Qumran document 4Q401 "Songs of the Sabbath Sacrifice" or "The Angelic Liturgy" (11:3 and 22:3) corroborate that Melchizedek is a character who leads the "El'ohim," which is the name used in canon for "angelic," "divine," or "princely" ministerial beings. It is also the name which the author of the Dead Sea Scroll document 11Q13 or "11QMelch" replaces in Psalms 82:1 with the name Melchizedek, implying that they are the holiest individuals below El'Elyon himself. There is reference in scroll 11Q13, again, to "the men of the lot of Melchizedek" who will be atoned for in the end times. Structuring of the name of each angel, whereby they end with "el," reveals individual rank titles that correspond with the name of the Order (El'ohim), rather than personal names. This gives credence to the idea that "Gabri'el," the 'angel' subordinate to Micha'el who visited Mary to tell her of her coming miraculous conception, was in fact a mortal man just like others in the Order of Melchizedek. In as much, it is most likely the case that David was not referring to Jesus 'the redeemer' (messiah actually translates as "anointed one") when he spoke of "my Lord," who was addressed by the Lord, in Psalms 110:4. Most probably, he was speaking of a priest in his service (or rather a priest who he served) who was ordained in the Order of Melchizedek, likely a descendent of Aaron named Zadok (I Kings 1:34, I Kings 2:35, I Kings 4:2, etc; 1 Chronicles 24:3, Book of Numbers 25:13, Book of Exodus 28:01). Such a priest would indeed be his "Lord," as David, like all in the line of Abraham, owe the Order of Melchizedek their allegiance as aforementioned, and therefore owe any priesthood wrought from said divine blessing the same allegiance. This explicitly denotes that the rank stations/positions of priests in the Order are considered timeless, hence why "angelic" or "ministerial" monikers are referenced as immortal. There would be, then, a certain degree of overconfidence in the men of the lot of Melchizedek that their Order will last through the end of time. But there is most probably another equally intriguing definition of "immortality" at play for the anointed priests of the Order, perhaps not so much in place of, but simultaneously existing with, that given so far.

It turns out that various species of Acacia, the type of wood used most for sacred purposes in the Bible, contain the most potent hallucinogenic substance known to man, that is DMT (Callaway 1988; Rätsch 1998: 28-30; Shanon 2008:58-70); many of these are used without secrecy in Africa, India, and Southern Europe. That being said, there is another plant, more ubiquitously presented throughout the art and literature of Biblical history, whose chemistry is less quantitatively potent but whose effect is still and differentially awe inducing, and quite literally visionary. It is the *Amanita muscaria* mushroom, found in pine forests worldwide and used through time immemorial by a myriad of cultures (Rätsch 1998: 630-641). Academics have certainly had evidence to propound the divulging of knowledge that it was used by Biblical era figures in years past (Irvin and Herer 2008; Irvin, Rutajit, and Zervos 2009; Rätsch 1998:632), and a publisher of elegantly copied "illuminated manuscripts" has provided the world with the same revelation in stunningly brilliant illustrated 14th Century scriptural form (© M. Moleiro Editor, www.moleiro.com), revealing that psychoactive mushrooms were considered by certain European monks to be holy (image revealed later in this article). And still, a more recent production from highly educated authors on a private literary and physically investigative endeavor has contributed a great deal more to the knowledge base (Brown and Brown 2016) by describing some widespread Early-to-Middle-Ages painted and sculpted renditions of Biblical characters - including Jesus and Gabri'el - using *Amanita* mushrooms, throughout Western and Eastern (Byzantine) Christendom.

It is a cross-cultural reality that experiences with *Amanita* mushrooms do not vary much from a dream-like trance induction wherein the experiencer will lose their sobriety, and either engage actively with visually manifested mentations ("hallucinations"), hear voices and/or natural or unnatural sounds, have Out of Body Experiences (OOBEs), or even undergo what feels like supernatural judgment or empowerment. Experienced shamanic practitioners of any given cultural community are usually those either strong enough in nerve, and/or who prescribe to safety conferring ritual discipline, to endure let alone desire such experiences more than once (Bombaci 2012). Shamans of various cultures, including Horus-worshipping priests of Amen-Ra in Biblical era Egypt (Berlant 2005; Brown and Brown 2016:209-210), consider psychoactive mushrooms to be a sort of agent or spirit of the underworld, or gateway to the numinous realm, which implies that the experience itself is that of death and then rebirth (upon sobering). It can be reasonably assumed that priests in the Order of Melchizedek would hold the same regard (Peoples, Duda, and Marlow 2016; Vitebsky 1995:88-90, 94-95; Winkelman 1996), and deem themselves "immortal" in that they have survived death and know what awaits them, as well as how best to prepare for it and be masters of that realm (through continued ritual practice).



A blaring clue. "Abraham meets Melchizedek" mosaic section with *Amanita muscaria* mushroom cap displayed prominently in lower right, as a symbolic key for identifying to the initiated what types of "bread" and "wine" were consumed for the consecration of Melchizedek's blessing upon Abraham (roasted *Amanita* caps lose their red and become tan, and exude detoxified wine-colored liquid - which may or may not indicate that the "wine" was also an *Amanita* product). Note the focus of the gazing squire behind Abraham on the left: the *Amanita* cap in *grail* on bottom right. Notice also the behavior of the servants on the right: one is surreptitiously pouring out wine as he takes a handful of *Amanita* mushroom, as the other cautiously gazes at the viewer. Relatively, but in speculative interpretation, it might be intuited that the term "scales," used to describe that which fell from Paul's eyes when Ananias of Damascus "healed" him of his hallucinatory "blindness" (Acts 9:18) and then sent him to proselytize, was not to be understood as reference to some physical material or disease (which would be odd by any account, because such a disease is not known of now, and because his military unit did not recount seeing anything wrong with him at all), but rather to the shedding of some *experience*; that is, it might well be that Paul was intentionally given a rather heavy dose of *Amanita* extract by a covert Christian sympathizer in his military unit of persecutors in order to conduct a psychological operation to coerce his highly useful religious conversion. After all, the "voice of Jesus" commanded Paul to Damascus where "the Lord" told Ananias to heal Paul so that he could become his "chosen instrument to proclaim [his] name to their kings and to the people of Israel" (Acts 9:15), acting as the 'witness' of "the Righteous One" (Acts 22:14), a title which is alias for Micha'el Melchizedek, as we know, who has indeed been depicted throughout Catholic canon as a winged judge weighing souls on a *scale* in his role as gatekeeper to Heaven. In as much, Paul was made to believe he was at the gates of Heaven in between life and death. This exegetical interpretation makes sense, and the accusation is far from outlandish, given how "Ananias" was the exact name of 'two' men involved with the orchestration of separate Christianity-bolstering miracles in the Bible - this healing and preaching episode, and then one where he was a non-believer who purportedly died by way of a miraculously Christ-embued life taking power within Peter (Acts 5:5) - and still another man, a Pharisee high priest (likely the true identity of these 'three' men) who helped usher along Paul's eventual martyrdom by the

Romans (Acts 23:1, 24:5, 25:5, 27:30) [Bombaci 2017]. Thus, Paul was "blind" because he was literally in hallucinatory limbo, especially because he did not eat or drink anything for 3 days after being drugged (Acts 9:9), and he was then "resurrected" or healed from "blinding" judgment, likely with an antidote given to him by Ananias along with the food he ate which gave back his strength (Acts 9:19). People in the western world might call this psychological warfare today; however, such a fabulation is not uncommon amongst shamanistic and miracle cult groups of various cultures, as theatrics lend supernatural credence to the power of the initiated, allowing them to gain and maintain their status (Vitebsky 1995:120-124).

Though Paul's mis/adventure seems to be an aside, it is worth mentioning here because of the way in which immortality was an already acceptable and in fact promoted notion amongst both Pharisee Jews and Roman Emperors. Officials of the former preached that angels, spirits, and resurrection are all real phenomenon (Acts 23:8 - in opposition to beliefs of the Saducees, their Jewish sectarian competition), and 36 of 60 emperors of the latter called themselves *diius* (the culturally syncretic and Roman term for the highest of Gods) [Atwill 2011:37] all the way through the Papacy whereby Popes are considered the "Vicar" (literally, *replacement* or *stand-in*) of Christ. So then, it was apparently no revolutionary event for Christianity to become the official religion of the Roman Empire, but the same can be said for how it would gain more influence than the Judaism of the Pharisees, in that their faith, with its supernatural stances, could yet be defended and compatible with Christianity while Saducees became less favored, and, because the violent messianic Sicarii zealots amongst them, causing war between *all* Jews and Romans, would be stymied to silence and yet serve to stigmatize Jews as a whole. The Roman Empire would in turn 'graft' itself to the branch or *nazor* of David (hence the term "Nazorean") and be crowned successor of its lineage [Atwill 2011:219-263] in both Holiness and dominion, wherein all emperors would receive the title of Pontifex Maximus, making each one in rule the high priest "of the Roman religion and the official head of the Roman college of priests - the same title and office that, once Christianity had become the Roman state religion, its popes would assume" [Atwill, p35]. As of modern day, this power has affected billions of people around the world and is recognized by many (including the Vatican's own Congregation of the Doctrine of the Faith) as higher in authority than kingdoms and governing establishments alike [Robbins 1999:114-132]. Immortal, indeed - and with sequential rulers that are each living stand-in icons, resurrections as it were, of the original High Priest Melchizedek, while also representing the original Roman *diius* (Bombaci 2017).

Also easing the appropriation of the visionary religion into official State ministry was the fact that, in many cases, Dionysian and Apollonian worship in Greco-Roman times involved the use of psychoactive *Amanita* mushrooms, two of which bear the variant names of *Amanita regalis* (Fr.) "Michael" and *Amanita caesarea* [Rätsch 2005:632-633]. However, as with elite use in the pre-Columbian world [Rätsch 2005:635], the official sacramental use of these *entheogens* (a term meaning "generator of God within") was kept secret beyond the enduring period of the Medieval Inquisition in the Old World through public portrayal of them as being dangerous or pagan and therefore heretical [Brown and Brown 2016:152-168]. It would dramatically affect the faith of Christian followers worldwide to be informed that the "bread" and "wine" of the Last Supper were actually psychoactive sacraments of the Order, which would consecrate the conferral of official priesthood upon Jesus' disciples, causing them to "be filled with the Holy Spirit" (Acts 2:4) and "speak in tongues" after the Ascension on the Day of Pentecost when imbibing it "with Jesus" (Matthew 26:29). "Speaking in tongues," by the Biblical description of the experience, is an adequate term for a phenomenon entirely familiar to those who have imbibed the psychoactive mixture of any entheogen and the tea of *Syrian Rue*, a revered plant used throughout the Middle East as both medicine and as royal red dye, which contains a hallucinogen-activating chemical, harmine, once called *telepathine* [Rätsch 2005:425-428, 638-639]. Indeed, "speaking in tongues" is considered an act of the most Holy where the "speaker" gains "all kinds of speech and all kinds of knowledge" (1 Corinthians 1:5) and can communicate directly with God (1 Corinthians 14:2) while being considered insane by onlookers (1 Corinthians 14:23). That the disciples were not actually speaking other *languages*, but were rather using *all kinds of speech*, as quoted above, is denoted in Acts 2:13 whereby some onlookers pointed out that the disciples must have been "full of *new* wine" (KJV).

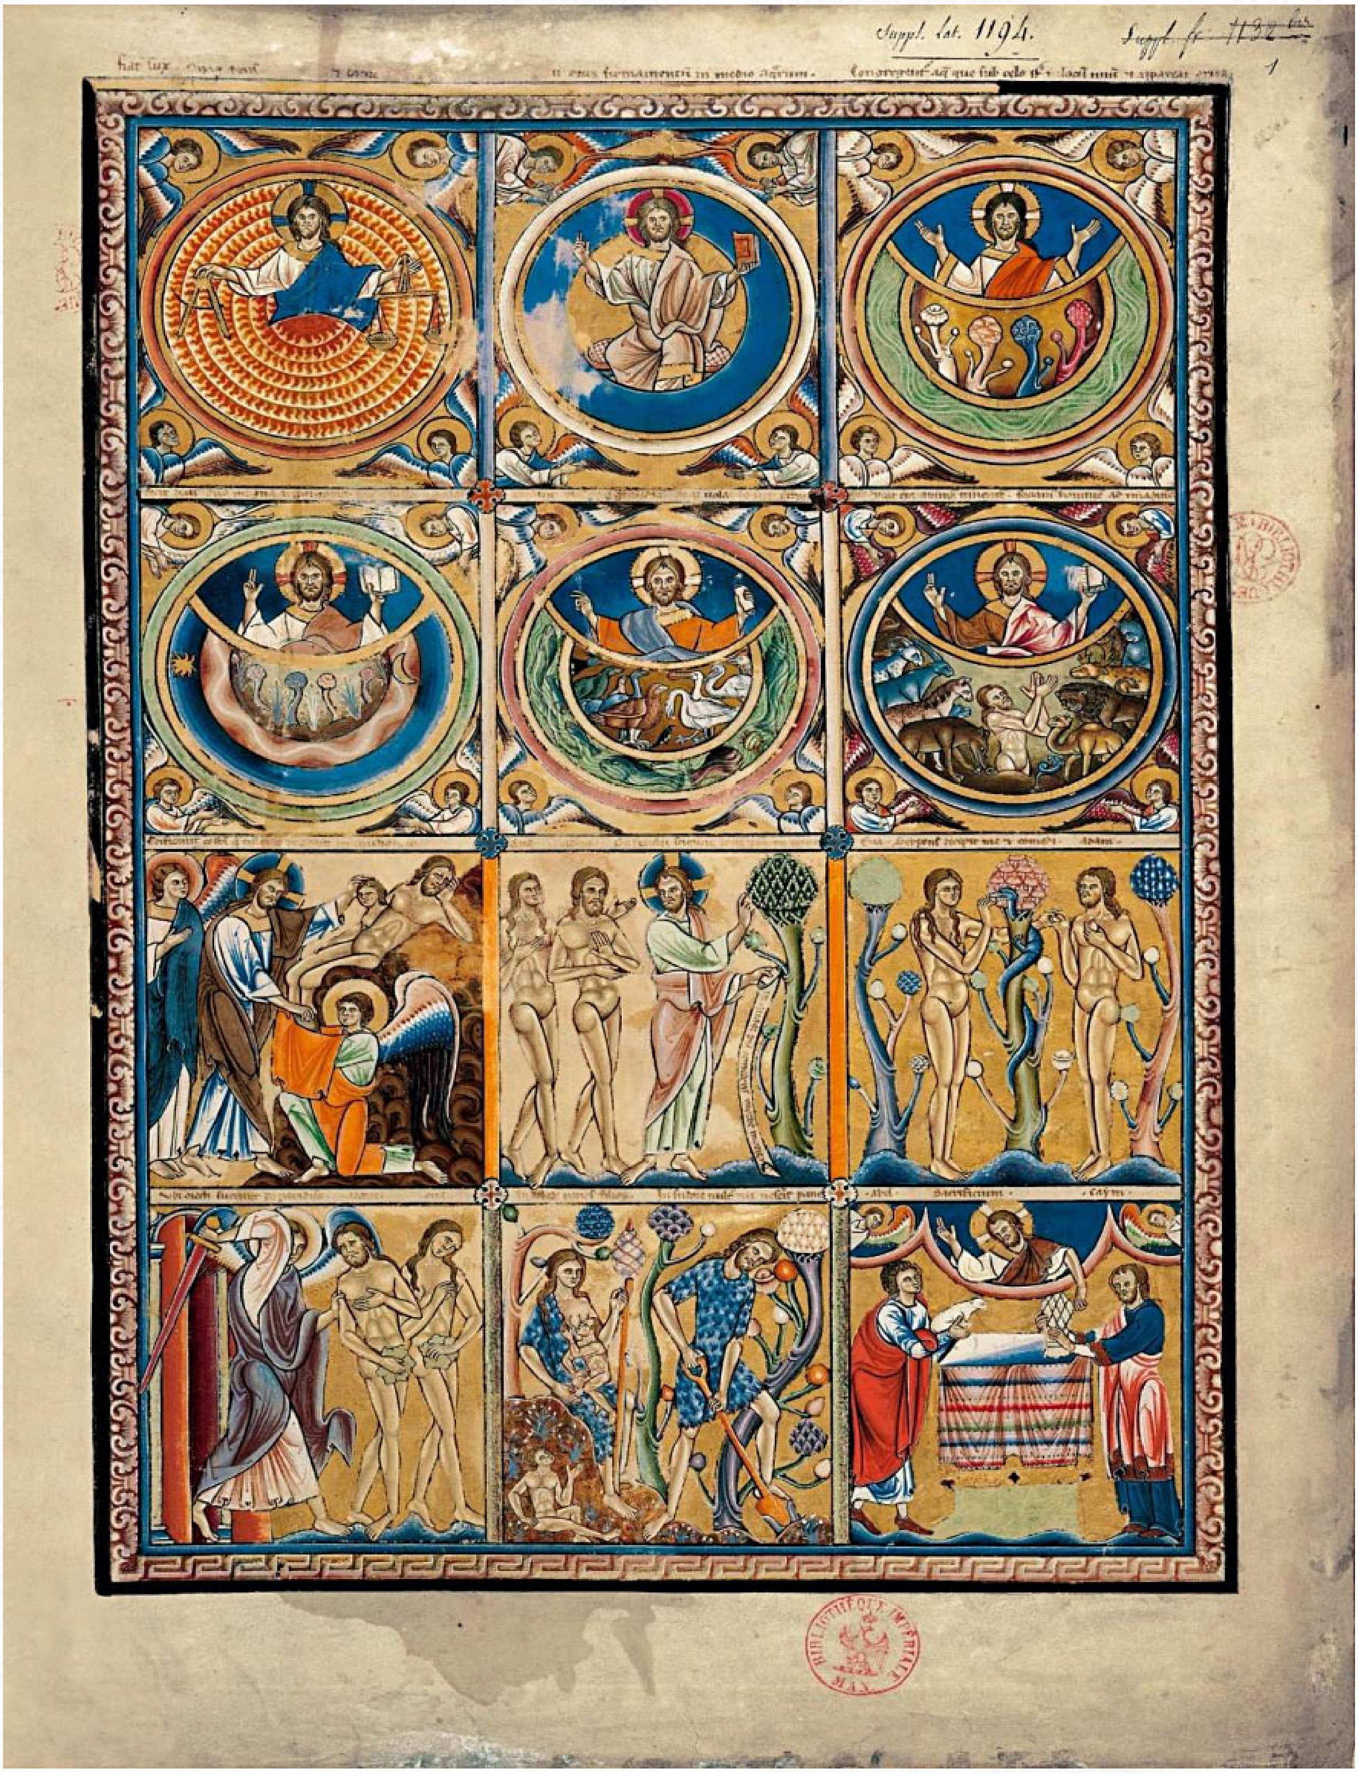
Note the hand-veiled manner in which the disciple is receiving the sacrament, symbolic of the white *veil* on the underside of *Amanita* mushroom caps; this is common practice with the sacrament (Brown and Brown 2016), and is seen also in the previous image of Melchizedek and Abraham. The mixing of wine with spices to increase intoxication is written of throughout the Bible (Isaiah 5:22 & 65:11, Psalm 75:8, Proverbs 23:30), and, as we know it is fallacy that new wine is innately more potent than old wine (in any manner but purity), the onlookers' proclamation implied two things: they were at least novice polyglots whereby they knew that what they were hearing was not actually foreign languages (such as Arabic), and they were also keen to entheogenic intoxication, *though the psychoactive effects they were witnessing were perhaps of a* "*new*" *or rather* unfamiliar *type*. Indeed, as the Weymouth New Testament translation clarified the Bible for 19th Century English-speakers, Jesus actually said, in Matthew 26:29, "I will never again take the produce of the vine until that day when I shall drink the *new wine* with you in my Father's Kingdom," i.e., during entry into and after his "Ascension," i.e., the onset and peak of his entheogenic experience in "Heaven." More to the point, when Peter retorted to the onlookers that he and the disciples were not drunk, as "it was yet early in the morning" (Acts 2:15), he would not have been lying if indeed they had consumed the sacramental entheogenic admixture rather than alcohol, and, his retort therein reveals both his defiance against needing to abide layfolk norms due to his status in sacred discipleship, as well as his fervent belief that there is truly divinity in the rite. The holiest person they knew of had told them at the Last Supper that this *new wine* was not wine at all, but the "blood" of the new Covenant (Matthew 26:28), while the sharing of the bloodline was symbolic of resurrection or perpetuation of the Priesthood - just as symbolic, really, as the "rebirth" or "awakening" from the entheogenic experience itself. "Drunk" was certainly not the word for their condition. *Illuminated* is more appropriate. And illumination was exactly the point of the *timma* in the Dionysian celebrations and the *pharmakos* in the Eleusinian Mysteries (meaning 'to rub or pound,' and 'drugged wine,' respectively), which were exapted from the Greek pharmacotheon by the Romans for holy communion, the former of these known as being psychoactive and the latter surely containing ergot alkaloids - the precursors to LSD (Muraresku 2020). "To this day all visitors to Saint Paul's Monastery on Mt. Athos in Greece, one of the most important sites of Orthodox [Christian] spirituality, will come face-to-face with a beautiful Greek saying mounted on the wall of the reception area: "If you die before you die, you won't die when you die" (Muraresku 2020:11).

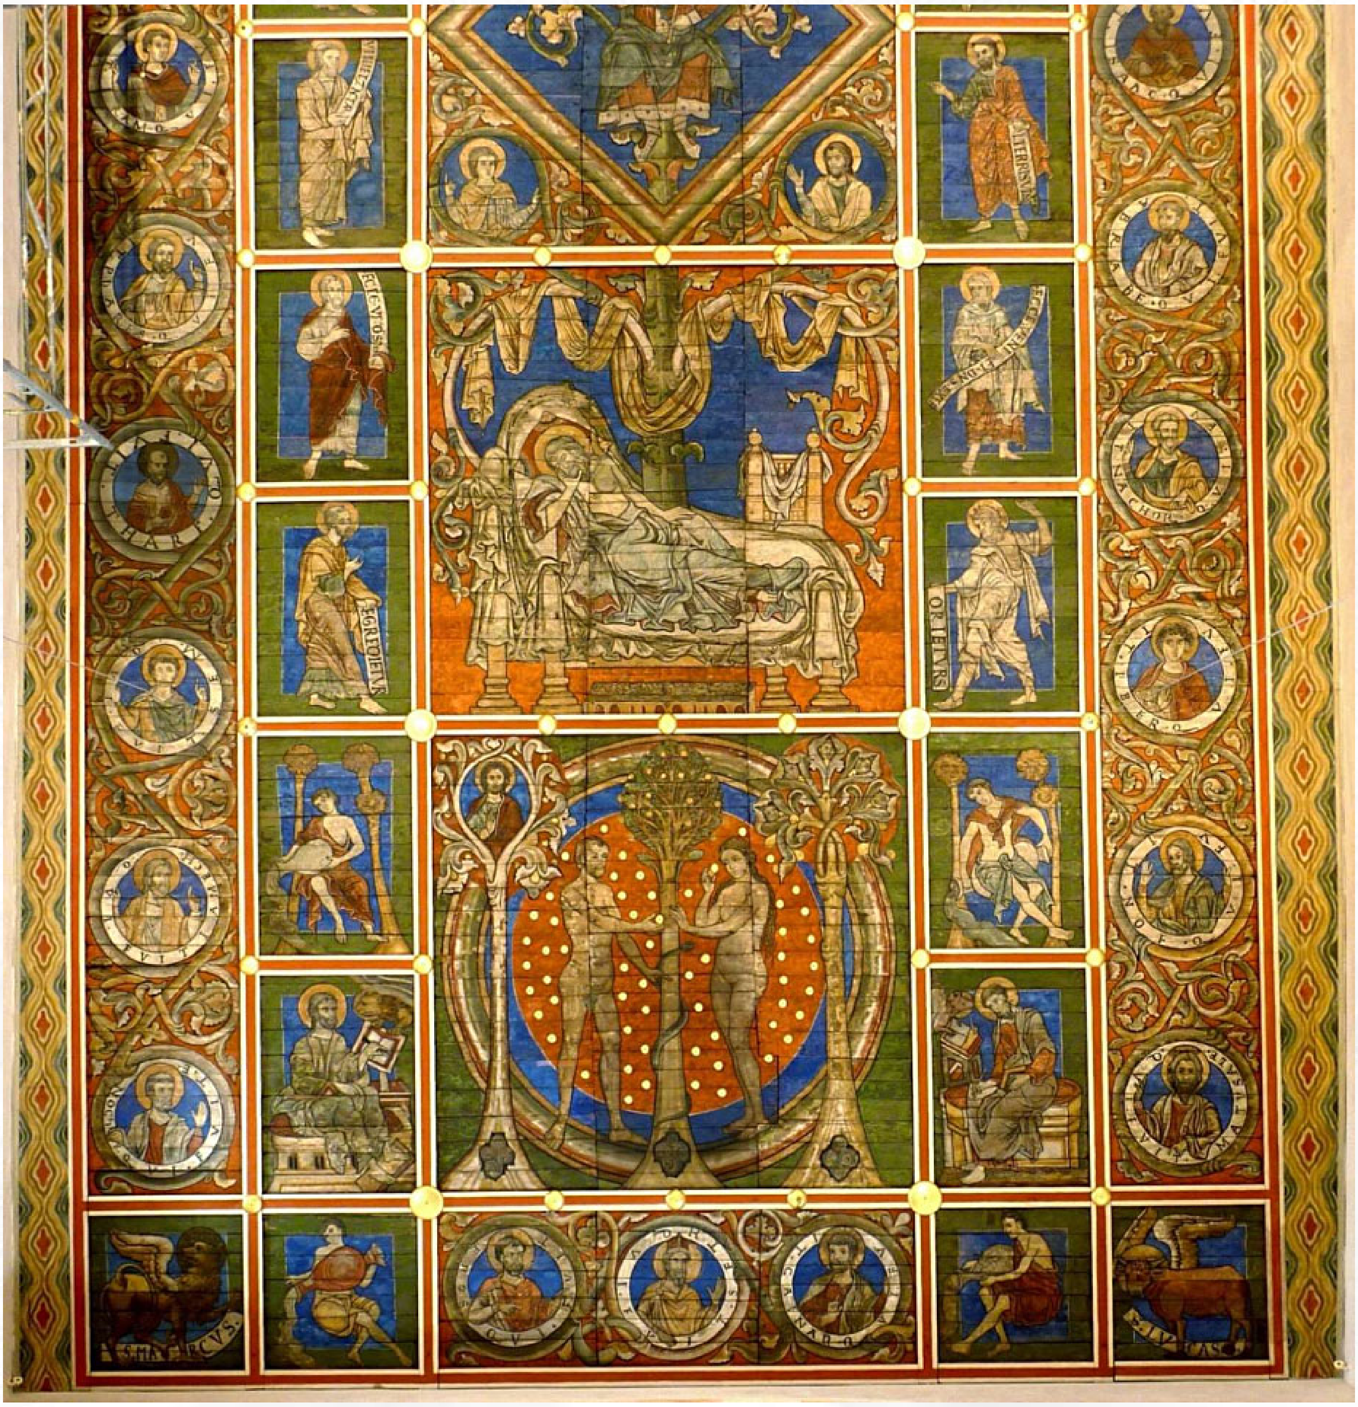
It would likewise be of shocking impact for the faithful today to see the mural painting of the *Amanita* "sponge" being offered to Jesus upon the cross before his death and *resurrection*, at the Dark Church in Göreme, Turkey (Brown and Brown 2016:190), or the mural painting of *Amanita* mushrooms held in the hands of the angels Gabri'el and (probably) Micha'el in the Yilanli Church of Ilhara Valley, Turkey (shown heretofore, but also more fully revealed in the photo by Martin Siepmann via AGE Fotostock, website in References Cited). That Jesus' resurrection was a metaphor, for enlighteningly awe-striking entheogenic experiences and the *blessing* of being returned therefrom, is further revealed by inter-textual analysis of the contradicting *physical* Resurrection account as differing between the Gospels of Matthew, Mark, Luke, and John:

> "the four Gospels each give a different time for the first visit to Jesus' tomb, though they all agree that a character named Mary Magdalene is the first visitor. The four Gospels also contradict one another about whether Mary Magdalene is alone when she first comes to the tomb, and about how many individuals are either inside or outside the tomb when she arrives. [...] Keeping in mind the ancient Hebrew tradition of reading their literature intertextually, it is congruent that the Romans would use this technique for their lampoon. Mistake one another for angels, and thereby delude themselves into believing that their Messiah has risen from the dead." [Atwill 2011:187]

This is elucidated in logistical / schematic literary analysis to be true [Atwill 2011:187-219]. The 'lampoon' Atwill refers to is that whereby the imperial Flavian family outwitted the zealots through clever storytelling to have them believe not only that their prophesied militant messiah was actually a Gnostic pacifist (Internet Sacred Texts Archive 2010), but that he was now deceased though immortally a judge over all who do not abide such pacifist ways, i.e., *him* being Rome itself, a la the standing Pope, or Vicar of its realm. It is then a sort of taunt about the immortal success of this obfuscation, that the *Amanita* symbolism would arise as an esoteric clue in plain sight about Jesus' resurrection, i.e. in Christmas festivity via concurrent celebration of Saint Nicholas or "Santa Claus" (Main 2013; Vitebsky 1995:70-73, 82-84) - a purportedly fabled and secular but actually historical Catholic figure thought to be imbued with post-mortem supernatural powers (de Ceglia 2012), and who is most commonly recognized and unfortunately belittled as whimsical rather than truly representational, because of the occulting cultural syncretism that went into creating his story and image. Importantly, Saint Nicholas was integral to the signing of the Nicene Creed that established the modern Trinitarian doctrine and the Catholic Church.



"Scenes from the Old Testament: Genesis," in the 14^{th} century *illuminated manuscript* called the Great Canterbury Psalter (f. 1r), the original of which was meticulously copied and reprinted by Moleiro (© M. Moleiro Editor, www.Moleiro.com). Note image of El'Elyon ("God") guiding Adam and Eve to the green colored Fruit of the Tree of Life, followed by image of their Original Sin in eating from the Fruit of the Tree of Knowledge, white-spotted and red in comparison. The visage of the latter is muddled by the 'topiary' illustration style used for *all* plants, common in art from this time period, making it easy to obscure the *Amanita*'s involvement with Christendom.



"Hildesheim, St. Michael's church - Painted wooden ceiling from about 1230 CE. The painted wooden ceiling of the nave is a rare and beautiful survival, dating from 1230. [...] It depicts the Tree of Jesse (the family tree of Christ). Also pictured are 42 circular medallions of the ancestors of Christ; 40 square or rectangular fields are (...) flanking the central picture panels with representations of the Four Evangelists and their symbols, the Four archangels, the Four Rivers of Paradise and many prophets. The area showing Christ enthroned is the only part that is not original - that section of the ceiling collapsed in 1650 and was remade in 1960" - *Petrus Agricola*. The mural blatantly depicts Adam and Eve picking the white spots from an *Amanita muscaria* cap, with the mushroom being identified *in association with* a coniferous tree or cedar, around which the "talking" serpent is coiled. *Amanitas* do in fact primarily grow under such trees throughout the world, and, with spore reproduction being unknown before scientific advances, their origins were elusive to historic people, seeming to be from the trees themselves - *as fruits*. Amanita sacrament use in the Order of Melchizedek is revealed by murals in various Catholic churches (Irvin and Herer 2008; Irvin, Rutajit, and Zervos 2009), and in a Medieval "Illuminated" Bible called The "Eadwine" or "Great Canterbury" Psalter (© M. Moleiro Editor, www.moleiro.com), of The Temptation of Adam and Eve wherein they are portrayed as eating *not* "fruit" from a magic tree but from blatant macro representations of *Amanita* mushrooms. This would imply that Original Sin itself is derived from entheogenic enlightenment, and, in association with its use as the Holy sacrament, that the most disciplined religious use of *Amanita* - for repeated communication with God that occurred upon their consumption of it, and therefore to receive forgiving divine guidance - is the only path to redemption. Considering that the potent psychoactive substances *Boswelia* (the active ingredient in Frankincense, an antidepressant/euphoriant), and cannabis (*knei bosem* in Hebrew, a euphoriant/hallucinogen), were used frequently in a fashion inducing acute exposure for purification and access to the numinous in religious rites of the Old Testament (Shanon 2008:69), the *Amanita* was therefore but one magical substance in a divine mixture. As regards the botanical identification of knei bosem, the use of *Cannabis sativa* in Egypt since the time of Moses is indisputable (Rätsch 2005:148), and it was used contemporaneously by people of nearby countries for religious and hedonic purposes as well.

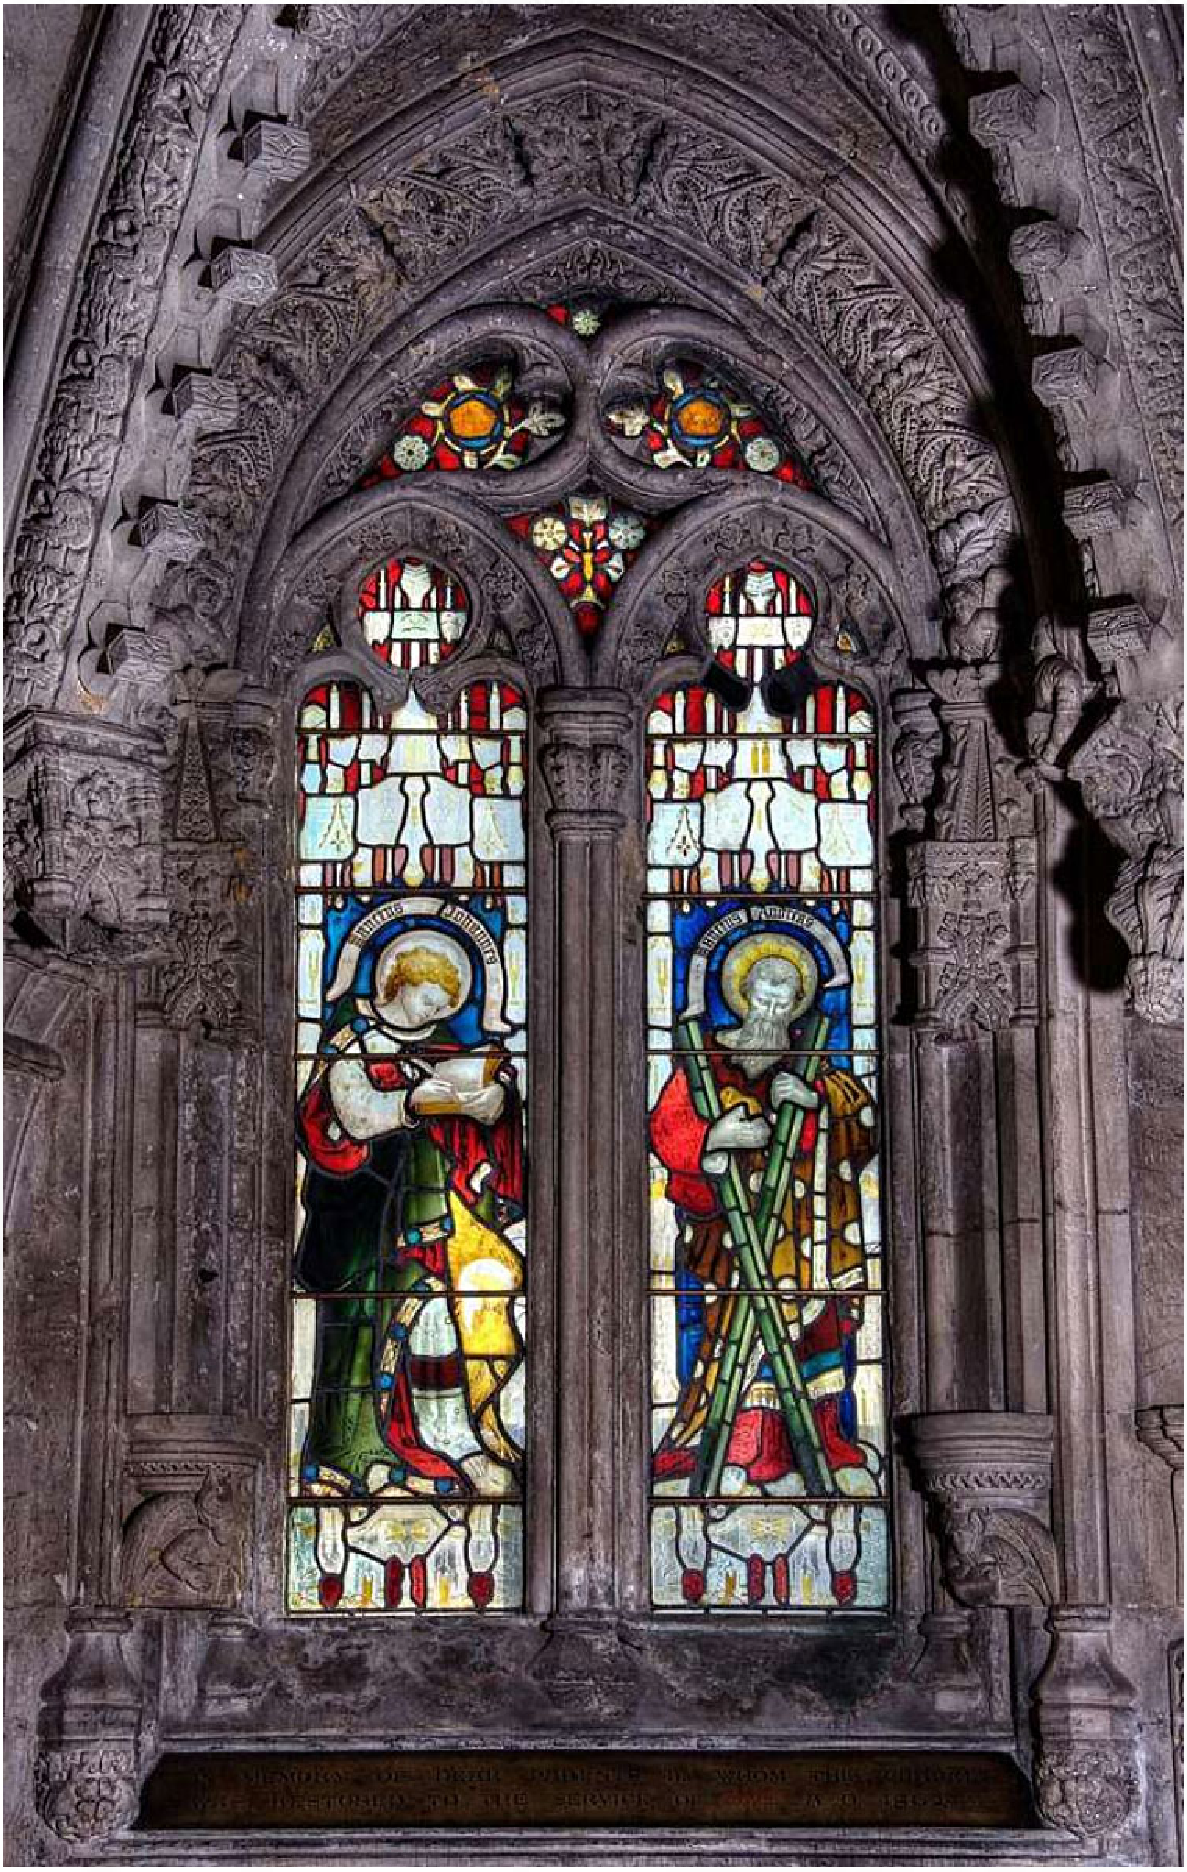
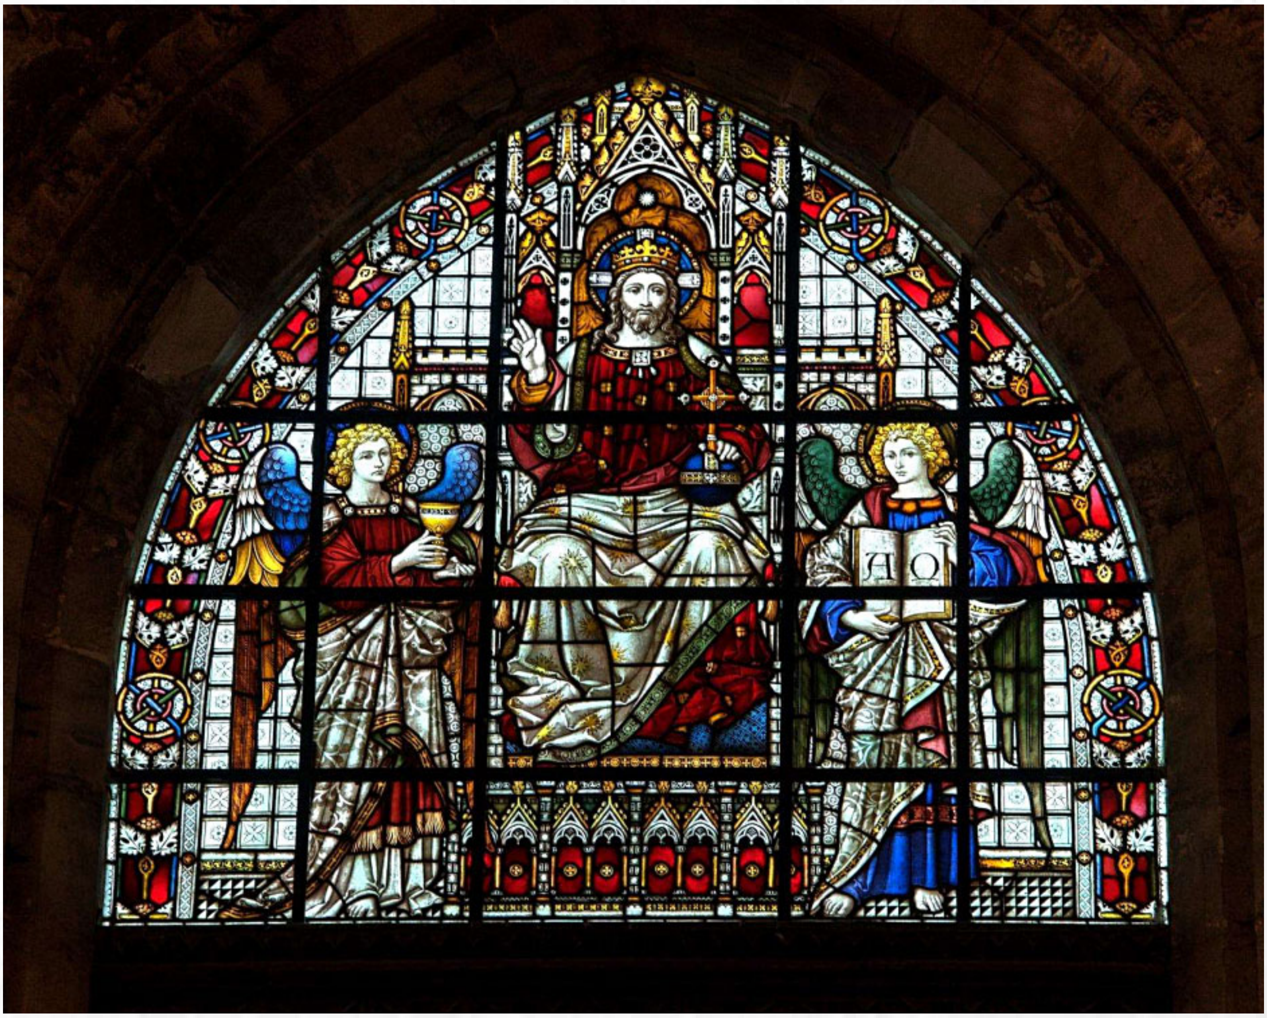
Given the widespread and common nature of ancient entheogenic rites in the varying religions throughout the region, it is apparent what exactly this refers to. Such a premise would explain why the Holy Inquisition was initiated, as the Church was encountering more and more numerous reports of pagan people utilizing entheogens. Hence began the trials of "witches" and "heretics," given that pagans were not typically literate and therefore not considered capable of being as Holy as Church officials - a reality that likely gave these officials the sense that pagans were profaning their Holy Sacrament and therefore also the true spiritual pathway to God itself. This premise would also explain why Jesus is canonized as being entirely necessary for pagans to receive redemption and thence acceptance into Heaven, as his Trinitarian role is the supernatural mediator between God and the people whose descendants bear the mark of Original Sin and therefore displease Him. The trouble with this doctrine is that he is considered immortal by virtue of, or rather, by the original erring interpretive testimony of Luke 1:26-38, purporting that he was the son of God. Through this overall exegetical analysis, we know now the origin of the proclamation of Jesus' immortality as well as the meaning behind holy resurrection. So, the whole Trinity Doctrine falls apart as the dark gaps are thus filled. Or rather, it is a fallacious doctrine that Jesus alone can do the saving or that he is even required for it.



In a 15th Century church of the Knights Templar, Rosslyn Chapel (Scotland), is this stained glass art presented for focus on Saint Andrew on right window panel, wearing *Amanita* styled robes. Of note, as he was an apostle and the brother of fellow apostle Saint Peter. Photograph copyright by Vic Sharp (www.mistyriver.co.uk), original available for viewing on his Flickr portfolio.



Also in Rosslyn Chapel, is this stained glass window depicting Jesus enthroned as "priest forever in the Order of Melchizedek," wearing regalia fashioned as an *Amanita* mushroom, with symbolically *gold*-spotted red robe (rather than white, likely to denote Order status) and white 'veil' below; El'Ohim at his sides. Emulation of mutually ideal goodness and compassion was the message of Jesus the preacher in the gospel of Matthew. However, the Nag Hammadi texts found in the deserts of Egypt in 1945 added clarity to these teachings via the Gospel of Thomas whereby Jesus is quoted at length on the topic of gnostic *self-identification* with God. One famous passage is this:

> "I am the light that is over all; I am the All. The All came forth out of me; and to me the All has come. Split a piece of wood - I am there; lift the stone, and you will find me." [Logon 77, in Patterson and Robinson 1998]

However, Jesus also said that

> "The person old in his days will not hesitate to ask a child seven days old about the place of life, and he will live; for many who are first will become last, and they will become a single one" (Logon 4, ibid), whereby "The one who seeks should not cease until he finds; and when he finds, he will be dismayed; and when he is dismayed, he will be astonished; and he will be king over the All" (Logon 2, ibid).

This is profound, and yet there is another and more truly explicit passage on gnosis:

> "If those who lead you say to you: 'Look, the kingdom is in the sky!' then the birds of the sky will precede you. If they say to you: 'It is in the sea,' then the fishes will precede you. Rather, the kingdom is inside of you, and outside of you. When you come to know yourselves, then you will be known, and you will realize that you are the children of the living father. But if you do not come to know yourselves, then you exist in poverty, and you are poverty." [Logon 3, ibid]

And it is a certain poverty that most spiritual people feel when they pray but God does not *seem* to correspond. As Saint Thomas Aquinas said, "For those with faith, no evidence is necessary; for those without it, no evidence will suffice." In scientific analogy, the Golden Ratio may be a biological truth, but represents a never-ending spiral - an irrational value, the type of which makes us always reach for more knowledge without ever seeing that we could already be holding the penultimate and concise version of it if only we gave more credence to pattern recognition. Of course, we are beginning to do exactly that, in this increasingly AI-imbued epoch. Entheogenic initiatory rites that reveal abstract naturalistic truths and resurrect one into gnostic self-realization can both inspire and reify reverent beliefs and show the path of humanitarian and ecological redemption. They should therefore not be reserved for "the men of the lot of Melchizedek" either now or at the end times should they ever actually come. It is the right of all to be so enlightened.

Foreword by R. Gordon Wasson

So much has been written about the Eleusinian Mysteries and for so long a time that a word is needed to justify this presentation of three papers dealing with them. For close to 2,000 years the Mystery was performed every year (except one) for carefully screened initiates in our month of September. Everyone speaking the Greek language was free to present himself, except only those who had the unexpiated blood of a murdered man on their hands. The initiates lived through the night in the telesterion of Eleusis, under the leadership of the two hierophantic families, the Eumolpids and the Kerykes, and they would come away all wonderstruck by what they had lived through: according to some, they were never the same as before. The testimony about that night of awe-inspiring experience is unanimous and Sophocles speaks for the initiates when he says:

> Thrice happy are those of mortals, who having seen those rites depart for Hades; for to them alone is granted to have a true life there. For the rest, all there is evil.

Yet up to now no one has known what justifies utterances such as this, and there are many like it. Here lies for us the mystery of the Eleusinian Mysteries. To this mystery we three have applied ourselves and believe we have found the solution, close to 2,000 years after the last performance of the rite and some 4,000 years since the first.

The first three chapters of this book were read by the respective authors as papers before the Second International Conference on Hallucinogenic Mushrooms held on the Olympic Peninsula, Washington, on Friday, 28 October 1977.

I. The Wasson Road to Eleusis

by R. Gordon Wasson

With this little book we begin a new chapter in the history of the fifty-year-old discipline of ethnomycology, a chapter that for the first time takes within its purview, and in a big way, our own cultural past, our legacy from ancient Greece. Ethnomycology is simply the study of the role of mushrooms, in the broadest sense, in the past of the human race; and it is a branch of ethnobotany.

The English language lacks a word to designate the higher fungi. "Toadstool" is an epithet, a pejorative designation embracing all those fungal growths that the user distrusts, whether rightly or wrongly. "Mushroom" is ambiguous, covering different areas of the fungal world for different persons. In this little book we will use "mushroom" for all the higher fungi. Now that at long last the world is coming to know these fungal growths in all their myriad shapes and colors and smells and textures, perhaps this novel usage will answer to a need and come to be generally accepted.

We are three who have enlisted for this presentation. Dr. Albert Hofmann is the Swiss chemist renowned for his discovery in 1943 of LSD, but his familiarity with the plant alkaloids is encyclopaedic and he will draw our attention to attributes of some of them relevant to the Eleusinian Mysteries.

As we are dealing with a central theme of Greek civilization in antiquity, it was obvious that we needed the cooperation of a Greek scholar. At the appropriate moment I learned of Professor Carl A. P. Ruck, of Boston University, who for some years has been making notable discoveries in the recalcitrant area of Greek ethnobotany. For many months we three have been studying the proposal that we are making and his paper will be the third and concluding one. *The Homeric Hymn to Demeter* is the source for the myth that underlies Eleusis and we offer a new English rendering of it by Danny Staples.

It will be my function, in this first of three papers, to stress certain attributes of the cult of inebriating mushrooms in Mexico.

Early Man in Greece, in the second millennium before Christ, founded the Mysteries of Eleusis and they held spellbound the initiates who each year attended the rite. Silence as to what took place there was obligatory: the laws of Athens were extreme in the penalties that were imposed on any who infringed the secret, but throughout the Greek world, far beyond the reach of Athens' laws, the secret was kept spontaneously throughout Antiquity, and since the suspension of the Mysteries in the 4th century A. D. that Secret has become a built-in element in the lore of Ancient Greece. I would not be surprised if some classical scholars would even feel that we are guilty of a sacrilegious outrage at now prying open the secret. On 15 November 1956 I read a brief paper before the American Philosophical Society describing the Mexican mushroom cult and in the ensuing oral discussion I intimated that this cult might lead us to the solution of the Eleusinian Mysteries. A famous English archaeologist specializing in the archaeology of Greece, with whom I had had the friendliest relations for about thirty-five years, wrote me in a letter a little later the following:

> I do not think that Mycenae had anything to do with the divine mushroom or the Eleusinian mysteries either. May I add a word of warning? Stick to your Mexican mushroom cult and beware of seeing mushrooms everywhere. We much enjoyed your Philadelphia paper and would recommend you keep as close to that as you can. Forgive the frankness of an old friend.

I am sorry that he has now joined the shades in Hades, or perhaps I should be happy that he will not be pained by my brashness in disregarding his well-meant advice.

My late wife Valentina Pavlovna and I were the first to use the term ethnomycology and we have been closely identified with the progress in this discipline over the past fifty years. That the reader may sense the drama of this our latest discovery I will begin by retelling the story of our mushroomic adventure. It covers precisely the last fifty years. It constitutes in large measure the autobiography of the Wasson family, and it has now led us directly to Eleusis.

Late in August 1927 my bride, as she then was, and I took our delayed honeymoon in the chalet lent to us by the publisher Adam Dingwall at Big Indian in the Catskills. She was a Russian born in Moscow of a family of the intelligentsia. Tina had fled from Russia with her family in the summer of 1918, she being then 17 years old. She qualified as a physician at the University of London and had been working hard to establish her pediatric practice in New York. I was a newspaper man in the financial department of the *Herald Tribune*. On that first beautiful afternoon of our holiday in the Catskills, we went sauntering down the path for a walk, hand in hand, happy as larks, both of us abounding in the joy of life. There was a clearing on the right, a mountain forest on our left.

Suddenly Tina threw down my hand and darted up into the forest. She had seen mushrooms, a host of mushrooms, mushrooms of many kinds that peopled the forest floor. She cried out in delight at their beauty. She addressed each kind with an affectionate Russian name. Such a display she had not seen since she left her family's *dacha* near Moscow, almost a decade before. She knelt before those toadstools in poses of adoration like the Virgin hearkening to the Angel of the Annunciation. She began gathering some of the fungi in her apron. I called to her: "Come back, come back to me! They are poisonous, putrid. They are toadstools. Come back to me!" She only laughed the more: her merry laughter will ring forever in my ears. That evening she seasoned the soup with the fungi, she garnished the meat with other fungi. Yet others she threaded together and strung up to dry, for winter use as she said. My discomfiture was complete. That night I ate nothing with mushrooms in it. Frantic and deeply hurt, I was led to wild ideas: I told her that I would wake up a widower.

She proved right and I wrong.

The particular circumstances of this episode seem to have shaped the course of our lives. We began checking with our compatriots, she with Russians and I with Anglo-Saxons. We quickly found that our individual attitudes characterized our respective peoples. Then we began gathering information, at first slowly, haphazardly, intermittently. We assembled our respective vocabularies for mushrooms: the Russian was endless, never to this day exhausted; the English, essentially confined to three words, two of them ill-defined - toadstool, mushroom, fungus. The Russian poets and novelists filled their writings with mushrooms, always in a loving context. It would seem to a stranger that every Russian poet composes verses on mushroom-gathering almost as a rite of passage to qualify for mature rating! In English the silence of many writers about mushrooms is deafening: Chaucer and Milton never mention them, the others seldom. For Shakespeare, Spenser, William Penn, Laurence Sterne (extensively), Shelley, Keats, Tennyson, for Edgar Allan Poe and D. H. Lawrence and Emily Dickinson, "mushroom" and "toadstool" are unpleasant, even disgusting epithets. Our poets when they do mention them link them to decay and death. We began to cast our net wider and to study all the peoples of Europe, not only the German and French and Italians, but more especially the peripheral cultures, out of the main stream, where archaic forms and beliefs survive longest - the Albanian, Frisian, Lappish, Basque, Catalonian and Sardinian, Icelandic and Faroese, and of course the Hungarian and the Finnish. In all our inquiries and travels we looked, not to the erudite, but to the humble and illiterate peasants as our most cherished informants. We explored their knowledge of mushrooms and the uses to which they put them. We were careful also to take the flavor of the scabrous and erotic vocabularies often neglected by lexicographers. We examined the common names for mushrooms in all these cultures, seeking the fossil metaphors hiding in their etymologies, to discover what those metaphors expressed, whether a favorable or unfavorable attitude toward our earthy creatures.

A little thing, some of you may say, this difference in emotional attitude toward wild mushrooms. But my wife and I did not think so, and we devoted most of our leisure hours for decades to dissecting it, defining it, and tracing it to its origin. Such discoveries as we have made, including the rediscovery of the religious role for the hallucinogenic mushrooms of Mexico, can be laid to our preoccupation with that cultural rift between my wife and me, between our respective peoples, between the mycophilia and mycophobia (words that we devised for our two attitudes) that divide the Indo-European peoples into two camps. If this hypothesis of ours be wrong, then it must have been a singular false hypothesis to have borne the fruit that it has. But it is not wrong. Thanks to the immense strides made in the study of the human psyche in this century, we are all now aware that deep-seated emotional attitudes acquired in early life are of profound importance. I suggest that when such traits betoken the attitudes of whole tribes or peoples, when those traits have remained unaltered throughout recorded history, and especially when they differ from one people to another neighboring people, then you are face to face with a phenomenon of deepest cultural implications, whose primal cause is to be discovered only in the well-springs of cultural history.

Our card files and correspondence kept expanding and in the end, sometime in the early 1940's, we sat down, Tina and I, and asked ourselves what we were going to do with all our data. We decided to write a book, but there were so many lacunae in our evidence that it would be years before we could put words to paper. In our conversations at that time we found that we had been thinking along the same lines, afraid to express our thoughts even to each other: they were too fantastic. We had both come to discern a period long long ago, long before our ancestors knew how to write, when those ancestors must have regarded a mushroom as a divinity or quasi-divinity. We knew not which mushroom(s) nor why. In the days of Early Man his whole world was shot through with religious feeling and the unseen powers held him in thrall. Our sacred "mushroom" must have been wondrous indeed, evoking awe and adoration, fear, yes, even terror. When that early cult gave way to new religions and to novel ways emerging with a literate culture, the emotions aroused by the old cult would survive, truncated from their roots. In one area the fear and terror would live on, either of a particular mushroom (as in the case of *A. muscaria*); or else, as the emotional focus through tabu became vague, of "toadstools" in general; and in another area, for a reason that we cannot now tell, it was the spirit of love and adoration that survived. Here would lie the explanation of the mycophobia vs. mycophilia that we had discovered. ("Toadstool", incidentally, was originally the specific name of *A. muscaria*, the divine mushroom, of a beauty befitting its divinity. Through tabu, "toadstool" lost its focus and came to hover over the whole of the mushroom tribe that the mycophobe shuns.)

It was in Mexico that our pursuit of a hypothetical sacred mushroom first achieved its goal. On 19 September 1952 we received in the post two letters from Europe: one from Robert Graves enclosing a cutting from a pharmaceutical journal in which there were quotations from Richard Evans Schultes, who in turn cited a number of 16th century Spanish friars telling of a strange mushroom cult among the Indians of Mesoamerica; the second from Giovanni Mardersteig, our printer in Verona, sending us his sketch of a curious archaeological artifact from Mesoamerica. It was exhibited in the Rietberg Museum of Zurich. The artifact was of stone, about a foot high, obviously a mushroom, with a radiant being carved on the stem or what mycologists call the stipe. Here was perhaps the very cult we were seeking, well within our reach. Earlier we had resolved that we would avoid the New World and Africa in our inquiries: the world was too large and our hands were full with Eurasia. But in a trice we changed our minds and the course of our studies, and we concentrated on Mexico and Guatemala. We had been postulating a wild mushroom as a focus of religious devotion, a fantastic surmise. Now here it was on our doorstep. All that winter we went racing through the texts of the 16th century Spanish friars, and what extraordinary narratives they give us! We flew down to Mexico in that summer of 1953 and for many rainy seasons thereafter. With wonderful cooperation from everyone in that country, on the night of 29-30 June 1955 we finally made our breakthrough: my photographer and friend Allan Richardson and I participated with our Indian friends in a midnight *agape* conducted by a shaman of extraordinary quality. This was the first time on record that anyone of the alien race had shared in such a communion. It was a soul-shattering experience. The wild surmise that we had dared to postulate in a whisper to each other years before was at last vindicated. And now, nearly a quarter of a century later, we are prepared to offer another mushroom, *Claviceps purpurea*, as holding the secret to the Eleusinian Mysteries.

That there might be a common denominator between the Mexican mushroom Mystery and the Mystery of Eleusis had struck me at once. They both aroused an overwhelming sense of awe, of wonder. I will leave to Professor Ruck the discussion of Eleusis but will quote one ancient author, Aristides the Rhetor, who in the 2nd century A. D. pulled aside the curtain for an instant when he said that what the initiate experienced was "new, astonishing, inaccessible to rational cognition", and he went on:

> Eleusis is a shrine common to the whole earth, and of all the divine things that exist among men, it is both the most awesome and the most luminous. At what place in the world have more miraculous tidings been sung, and where have the dromena called forth greater emotion, *where has there been greater rivalry between seeing and hearing?* [Italics mine.]

And he goes on to speak of the "ineffable visions" that it had been the privilege of many generations of fortunate men and women to behold.

This description point by point tallies with the effect on the initiate of the Mesoamerican mushroom rite, even to the "rivalry" between seeing and hearing. For the sights that one sees assume rhythmical contours, and the singing of the shaman seems to take on visible and colorful shapes.

There seems to have been a saying among the Greeks that mushrooms were the "food of the Gods", *broma theon*, and Porphyrius is quoted as having called them "nurslings of the Gods", *theotrophos*. The Greeks of the classic period were mycophobes. Was this not because their ancestors had felt that the whole fungal tribe was infected "by attraction" with the holiness of the sacred mushroom, and that mushrooms were therefore to be avoided by mortal men? Are we not dealing with what was in origin a religious tabu?

I would not be understood as contending that only these alkaloids (wherever found in nature) bring about visions and ecstasy. Clearly some poets and prophets and many mystics and ascetics seem to have enjoyed ecstatic visions that answer the requirements of the ancient Mysteries and that duplicate the mushroom agape of Mexico. I do not suggest that St. John of Patmos ate mushrooms in order to write the Book of the Revelation. Yet the succession of images in his Vision, so clearly seen but such a phantasmagoria, means for me that he was in the same state as one bemushroomed. Nor do I suggest for a moment that William Blake knew the mushroom when he wrote this telling account of the clarity of "vision":

> The Prophets describe what they saw in Vision as real and existing men, whom they saw with their imaginative and immortal organs; the Apostles the same; the clearer the organ the more distinct the object. *A Spirit and a Vision are not, as the modern philosophy supposes, a cloudy vapour, or a nothing: they are organized and minutely articulated beyond all that the mortal and perishing nature can produce. He who does not imagine in stronger and better lineaments, and in stronger and better light than his perishing eye can see, does not imagine at all.* [Italics mine. From The Writings of William Blake, ed. by Geoffrey Keynes, vol. III, p. 108]

This must sound cryptic to one who does not share Blake's vision or who has not taken the mushroom. The advantage of the mushroom is that it puts many, if not everyone, within reach of this state without having to suffer the mortifications of Blake and St. John. It permits you to see, more clearly than our perishing mortal eye can see, vistas beyond the horizons of this life, to travel backwards and forwards in time, to enter other planes of existence, even (as the Indians say) to know God. It is hardly surprising that your emotions are profoundly affected, and you feel that an indissoluble bond unites you with the others who have shared with you in the sacred agape. All that you see during this night has a pristine quality: the landscape, the edifices, the carvings, the animals - they look as though they had come straight from the Maker's workshop. This newness of everything - it is as though the world had just dawned - overwhelms you and melts you with its beauty. Not unnaturally, what is happening to you seems to you freighted with significance, beside which the humdrum events of everyday are trivial. All these things you see with an immediacy of vision that leads you to say to yourself, "Now I am seeing for the first time, seeing direct, without the intervention of mortal eyes."

Plato tells us that beyond this ephemeral and imperfect existence here below, there is another Ideal world of Archetypes, where the original, the true, the beautiful Pattern of things exists for evermore. Poets and philosophers for millennia have pondered and discussed his conception. It is clear to me where Plato found his "Ideas"; it was clear to those who were initiated into the Mysteries among his contemporaries too. Plato had drunk of the potion in the Temple of Eleusis and had spent the night seeing the great Vision.

And all the time that you are seeing these things, the priestess in Mexico sings, not loud, but with authority. The Indians are notoriously not given to displays of inner feelings - except on these occasions. The singing is good, but under the influence of the mushroom you think it is infinitely tender and sweet. It is as though you were hearing it with your mind's ear, purged of all dross. You are lying on a *petate* or mat; perhaps, if you have been wise, on an air mattress and in a sleeping bag. It is dark, for all lights have been extinguished save a few embers among the stones on the floor and the incense in a sherd. It is still, for the thatched hut is apt to be some distance away from the village. In the darkness and stillness, that voice hovers through the hut, coming now from beyond your feet, now at your very ear, now distant, now actually underneath you, with strange ventriloquistic effect. The mushrooms produce this illusion also. Everyone experiences it, just as do the tribesmen of Siberia who have eaten of *Amanita muscaria* and lie under the spell of their shamans, displaying as these do their astonishing dexterity with ventriloquistic drum beats. Likewise, in Mexico, I have heard a shaman engage in a most complicated percussive beat: with her hands she hits her chest, her thighs, her forehead, her arms, each giving a different resonance, keeping a complicated rhythm and modulating, even syncopating, the strokes. Your body lies in the darkness, heavy as lead, but your spirit seems to soar and leave the hut, and with the speed of thought to travel where it listeth, in time and space, accompanied by the shaman's singing and by the ejaculations of her percussive chant. What you are seeing and what you are hearing appear as one: the music assumes harmonious shapes, giving visual form to its harmonies, and what you are seeing takes on the modalities of music - the music of the spheres. "Where has there been greater rivalry between seeing and hearing?" How apposite to the Mexican experience was the ancient Greek's rhetorical question! All your senses are similarly affected: the cigarette with which you occasionally break the tension of the night smells as no cigarette before had ever smelled; the glass of simple water is infinitely better than champagne. Elsewhere I once wrote that the bemushroomed person is poised in space, a disembodied eye, invisible, incorporeal, seeing but not seen. In truth, he is the five senses disembodied, all of them keyed to the height of sensitivity and awareness, all of them blending into one another most strangely, until the person, utterly passive, becomes a pure receptor, infinitely delicate, of sensations.

As your body lies there in its sleeping bag, your soul is free, loses all sense of time, alert as it never was before, living an eternity in a night, seeing infinity in a grain of sand. What you have seen and heard is cut as with a burin in your memory, never to be effaced. At last you know what the ineffable is, and what ecstasy means. Ecstasy ! The mind harks back to the origin of that word. For the Greeks *ekstasis* meant the flight of the soul from the body. I am certain that this word came into being to describe the effect of the Mystery of Eleusis. Can you find a better word than that to describe the bemushroomed state? In common parlance, among the many who have not experienced ecstasy, ecstasy is fun, and I am frequently asked why I do not reach for mushrooms every night. But ecstasy is not fun. Your very soul is seized and shaken until it tingles. After all, who will choose to feel undiluted awe, or to float through that door yonder into the Divine Presence? The unknowing vulgar abuse the word, and we must recapture its full and terrifying sense.... A few hours later, the next morning, you are fit to go to work. But how unimportant work seems to you, by comparison with the portentous happenings of that night! If you can, you prefer to stay close to the house, and, with those who lived through that night, compare notes, and utter ejaculations of amazement.

I will convey to you the overwhelming impression of awe that the sacred mushrooms arouse in the native population of the Mexican highlands. In the Mazatec tribe where I ingested them for the first time these particular mushrooms are not "mushrooms": they stand apart. One word - *thain*^{3} - embraces the whole fungal tribe, edible, innocuous but inedible, and toxic, - the whole fungal world except the sacred species. The sacred species are known by a name that in itself is a euphemism for some other name now lost: they are ^{ʔ}*nti*^{1}*xi*^{3}*tho*^{3}. (In Mazatec each syllable must be pronounced in one of four tones or in slides from one tone to another, *1* being the highest. The initial ^{ʔ} is a glottal stop.) The first element, ^{ʔ}*nti*^{1}, is a diminutive of affection and respect. The second element, *xi*^{3}*tho*^{3}, means "that which leaps forth". The whole word is thus: "the dear little things that leap forth". But this word is holy: you do not hear it uttered in the market place or where numbers of people are assembled. It is best to bring up the subject at night, by the light of a fire or a *vela* (votive candle), when you are alone with your hosts. Then they will dilate endlessly on the wonders of these wondrous mushrooms. For this euphemistic name they will probably use yet others, a further degree of euphemism, the *santitos*, the "little saints", or again the "little things" in Mazatec. When we were leaving the Mazatec mountains on horseback after our first visit there, we asked our muleteer Victor Hernandez how it came about that the sacred mushrooms were called "the dear little ones that leap forth". He had traveled the mountain trails all his life and spoke Spanish although he could neither read nor write nor even tell time by the clock's face. His answer, breathtaking in sincerity and feeling, breathed the poetry of religion and I quote it word for word as he uttered it and as I put it down in my notebook at the time:

> El honguillo viene por si mismo, no se sabe de donde, como el viento que viene sin saber de donde ni porque. [The little mushroom comes of itself, no one knows whence, like the wind that comes we know not whence nor why.]

Victor was referring to the genesis of the sacred mushrooms: they leap forth seedless and rootless, a mystery from the beginning. Aurelio Carreras, town slaughterer in Huautla, when we asked him where the mushrooms take you, said simply: *Le llevan alli donde dios esta*, "They carry you there where God is". According to Ricardo Garcia Gonzalez of Rio Santiago, "To eat the mushrooms you must be clean: they are the blood of our Lord the Eternal Father." *Hay que ser may limpio, es la sangre de Nuestro Señor Padre Eterno.* These are Spanish-speaking villagers picked at random. They express religion in its purest essence, without intellectual content. Aristotle said of the Eleusinian Mysteries precisely the same: the initiates were to suffer, to feel, to experience certain impressions and moods. They were not to learn anything.

As man emerged from his brutish past, thousands of years ago, there was a stage in the evolution of his awareness when the discovery of a mushroom (or was it a higher plant?) with miraculous properties was a revelation to him, a veritable detonator to his soul, arousing in him sentiments of awe and reverence, and gentleness and love, to the highest pitch of which mankind is capable, all those sentiments and virtues that mankind has ever since regarded as the highest attribute of his kind. It made him see what this perishing mortal eye cannot see. How right the Greeks were to hedge about this Mystery, this imbibing of the potion, with secrecy and surveillance! What today is resolved into a mere drug, a tryptamine or lysergic acid derivative, was for him a prodigious miracle, inspiring in him poetry and philosophy and religion. Perhaps with all our modern knowledge we do not need the divine mushrooms any more. Or do we need them more than ever? Some are shocked that the key even to religion might be reduced to a mere drug. On the other hand, the drug is as mysterious as it ever was: "like the wind that comes we know not whence nor why." Out of a mere drug comes the ineffable, comes ecstasy. It is not the only instance in the history of humankind where the lowly has given birth to the divine. Altering a sacred text, we would say that this paradox is a hard saying, yet one worthy of all men to be believed.

If our classical scholars were given the opportunity to attend the rite at Eleusis, to talk with the priestess, what would they not exchange for that chance? They would approach the precincts, enter the hallowed chamber, with the reverence born of the texts venerated by scholars for millennia. How propitious would their frame of mind be, if they were invited to partake of the potion! Well, those rites take place now, unbeknownst to the classical scholars, in scattered dwellings, humble, thatched, without windows, far from the beaten track, high in the mountains of Mexico, in the stillness of the night, broken only by the distant barking of a dog or the braying of an ass. Or, since we are in the rainy season, perhaps the Mystery is accompanied by torrential rains and punctuated by terrifying thunderbolts. Then, indeed, as you lie there bemushroomed, listening to the music and seeing the visions, you know a soul-shattering experience, recalling as you do the belief of some early peoples that mushrooms, the sacred mushrooms, are divinely engendered by Parjanya, the Aryan God of the Lightning-bolt, in the Soft Mother Earth.

Someone has called mycology the step-child of the sciences. Is it not now acquiring a wholly new and unexpected dimension? Religion has always been at the core of man's highest faculties and cultural achievements, and therefore I ask you now to contemplate our lowly mushroom - what patents of ancient lineage and nobility are coming its way!

R. Gordon Wasson

II. A Challenging Question and My Answer

by Albert Hofmann

In July 1975 I was visiting my friend Gordon Wasson in his home in Danbury when he suddenly asked me this question: whether Early Man in ancient Greece could have hit on a method to isolate an hallucinogen from ergot that would have given him an experience comparable to LSD or psilocybin. I replied that this might well have been the case and I promised to send him, after further reflection, an exposition of our present knowledge on the subject, which I already suspected would support my tentative position. Two years have passed, and here now is my answer.

Ergot is the English name for a fungal growth, the "sclerotium" of a mushroom known to mycologists as *Claviceps purpurea* (Fr.) Tul. It is a parasite on rye and other cereals such as barley or wheat, and also on certain wild grasses. Other species of the genus Claviceps, viz *C. paspali* Stev. and Hall, *C. nigricans* Tul., and *C. glabra* Langdon, etc., are parasitical to many species and varieties of grasses. Ergot itself is not of uniform chemical composition: it occurs in "biological" or "chemical" races, differing from each other mainly by the composition of their alkaloidal constituents. (Chemists define "alkaloids" as nitrogen-containing alkaline substances that represent the pharmacologically active principles of many plants.) Thus in Switzerland there exist three varieties of ergot of rye: (a) in the Midlands a race containing mainly the alkaloid ergotamine, (b) in the Valais one with alkaloids of the ergotoxine group, and (c) in the Grisons a variety with no alkaloids at all. Furthermore in other kinds of ergot - growing on wheat, on barley, on millet, on lolium, etc. - there are wide variations in alkaloidal makeup, sometimes depending on geographical location.

By far the most important of all kinds of ergot is ergot of rye, purple-brown protrusions from the ears of rye. Ergot of rye (in scientific nomenclature: *Secale cornutum*) has been called in England "horned rye", "spiked rye", "spurred rye", but most commonly "ergot of rye", a translation of the French *ergot de seigle*. The word ergot is defined in the Petit Larousse as "*petit ongle pointu derriere le pied du coq*", "small pointed talon behind the cock's foot", but the derivation of the French word *ergot* is uncertain. Other French names are *blé cornu, seigle ergoté, seigle ivre*. In German there seem to be more variants than in other languages: *Mutterkorn, Rockenmutter, Afterkorn, Todtenkorn, Tollkorn*, and many others. In German folklore there was a belief that, when the corn waved in the wind, the corn mother (a demon) was passing through the field; her children were the rye wolves (ergot). In our context we observe that of these names, two, *seigle ivre* ("drunken rye") and *Tollkorn* ("mad grain"), point to a knowledge of the psychotropic effects of ergot. This folk awareness of the mind-changing effects of ergot shows an intimate knowledge of its properties, at least among herbalists, deeply rooted in European traditions.

Ergot of rye has a storied past. Once a dreaded poison, it has become a rich treasure chamber of valuable pharmaceuticals.

In the Middle Ages bizarre epidemics occurred in Europe costing thousands of people their lives, occasioned by bread made from rye contaminated with ergot. These epidemics took two forms, *Ergotismus convulsivus*, characterized by nervous convulsive and epileptiform symptoms, and *Ergotismus gangraenosus*, in which gangrenous manifestations leading to mummification of the extremities were a prominent feature. Ergotism was also known as *ignis sacer* ("holy fire"), or "St. Anthony's fire", because St. Anthony was the patron saint of a religious order founded to care for the victims of ergotism. The cause of these epidemics - bread contaminated with ergot - was not learned until the seventeenth century, and since then there have been only sporadic outbreaks of ergot poisoning.

Ergot was first mentioned as a remedy by the German physician Adam Lonitzer in 1582. He said it was being used by midwives to precipitate childbirth. The first scientific report on the use of ergot as a uterotonic agent was presented by the American physician John Stearns in 1808: "Account of the *pulvis parturiens*". But already in 1824 Dr. David Hosack, also American, recognizing the dangers of using ergot for accelerating childbirth, recommended that the drug be used only to control postpartum haemorrhage. Since then ergot has been used in obstetrics mainly for this purpose.[1] (This Dr. Hosack was a distinguished man. He was a physician to many of the eminent New Yorkers of his time, and he accompanied Alexander Hamilton to Weehawken heights for his fatal duel with Aaron Burr. This I learned from the admirable life of Hosack by Christine Robbins.)

The latest and most important chapter in the history of ergot deals with it as a rich source of pharmacologically useful alkaloids.[2] More than thirty alkaloids have been isolated from ergot and it is unlikely that many new ones will be discovered. Hundreds of chemical modifications of these natural alkaloids have been prepared and investigated pharmacologically. Today all these alkaloids are also available by total synthesis.

Medicinally the most useful alkaloids stem from ergot of rye. The first ergot alkaloid that found widespread therapeutic use was ergotamine, isolated by A. Stoll in 1918. It is the essential component of pharmaceutical preparations such as "Cafergot" and "Bellergal", medicaments against migraine and nervous disorders. Modern valuable ergot preparations are "Hydergine" developed by A. Stoll and A. Hofmann in the Sandoz laboratories in Basel, containing hydrogenated ergotoxine alkaloids, used in the treatment of geriatric disorders, and "Dihydergot" with dihydroergotamine as active component, for the therapy of circulatory disturbances.

Of special relevance to our problem here are the investigations into the alkaloid ergonovine, which is the specific uterotonic water-soluble principle of ergot. In 1932 H. W. Dudley and C. Moir in England discovered that water-soluble extracts of ergot, containing none of the water-insoluble alkaloids of the ergotamine-ergotoxine-type, elicited strong uterotonic activity. This observation led three years later to the isolation of the alkaloid responsible for this action simultaneously in four separate laboratories, which named it "ergometrine", "ergobasin", "ergotocine," "ergostetrine", respectively. The International Pharmacopoeia Commission proposed a name to be internationally accepted to replace these synonyms, viz. "ergonovine".

In 1937, starting with naturally occurring lysergic acid, I prepared ergonovine, which by its chemical composition is lysergic acid propanolamide. Lysergic acid is the nucleus common to most ergot alkaloids. It is extracted from special cultures of ergot and could also be prepared today by total synthesis if this procedure were not too expensive. I used the method developed for the synthesis of ergonovine for the preparation of many chemical modifications of ergonovine. One of these partly synthetic derivatives of ergonovine was lysergic acid butanolamide. This is used today in obstetrics, replacing to a major extent ergonovine, under the brand name "Methergine" to stop postpartum haemorrhage.

Another lysergic acid derivative that I synthesized in this context aiming to get an analeptic (that is, an agent with circulation- and respiration-stimulating properties) was lysergic acid diethylamide. Pharmacological examination revealed a fairly strong uterotonic activity in this compound, nearly as strong as ergonovine. In 1943 I discovered in self-experiments the specific high hallucinogenic potency of lysergic acid diethylamide, which became known world-wide under the laboratory code name LSD-25.

My interest in hallucinogenic agents, originating in 1943 from my work with LSD, brought me into personal contact with Gordon Wasson, pioneer ethnomycologist and also pioneer in the investigation of the ancient Mexican mushroom cult. From Roger Heim, then head of the Laboratoire de Cryptogamie and Director of the famous Museum National d'Histoire Naturelle of Paris, whom Wasson invited to study and identify in the field his sacred mushrooms, I received samples of them for chemical analysis. With my laboratory assistant Hans Tscherter I succeeded in isolating the hallucinogenic principles of the sacred Mexican mushrooms, which I named psilocybin and psilocin. With my colleagues of the Sandoz Research Laboratories, we succeeded in the elucidation of the chemical structure and the synthesis of psilocybin and psilocin.

Inspired by my talks with my friend Wasson and encouraged by our success with the hallucinogenic mushrooms, I decided to tackle also the problem of another psychotropic Mexican plant, *ololiuhqui*. With Wasson's help I obtained a large quantity of authentic *ololiuhqui* seeds of the two morning glories that the Mesoamerican Indians were using, seeds of *Turbina corymbosa* (L.) Raf. and *Ipomoea violacea* L. When we analyzed them we arrived at an unexpected result: these ancient drugs that we are apt to call "magical" and the Indians consider divine, contained as their psychoactive principles some of our already familiar ergot alkaloids. The main components were lysergic acid amide and lysergic acid hydroxyethylamide, both water-soluble alkaloids, closely related to lysergic acid diethylamide (LSD), as is evident even to the non-chemist. Another constituent of the *ololiuhqui* alkaloids was ergonovine, the uterotonic principle of ergot.

The psychoactive property of these simple lysergic acid amides, closely related to LSD, is well established. The question presented itself whether ergonovine, being not only an alkaloidal component of ergot but also of *ololiuhqui*, possessed hallucinogenic activity. In the light of its chemical structure this did not seem unlikely: it does not differ much from LSD. But one may ask why, if it is hallucinogenic, this astonishing fact has not been announced, in the light of its use over recent decades in obstetrics. Undoubtedly the answer lies in the extremely low dosage of ergonovine used to stop postpartum bleeding, *viz* 0.1 to 0.25 mg. The effective dose of lysergic acid amide is 1 to 2 mg by oral application. I decided therefore to test in a self-experiment a corresponding dose of ergonovine:

> 1 April 1976
> 12.20 h: 2.0 mg ergonovine hydrogenmaleinate, containing 1.5 mg ergonovine base, ingested in a glass of water.
> 13.00 h: slight nausea, same effect as I have experienced always in my LSD or psilocybin experiments. Tired, need to lie down. With eyes closed colored figures.
> 13.30 h: the trees in the nearby forest seem to live, their branches moving in a threatening way.
> 14.30 h: strong desire to dream, unable to do systematic work, with eyes closed or open afflicted by mollusk-like forms and feelings.
> 16.00 h: motives and colors have become clearer, but bearing still some hidden dangers.
> 17.00 h: after a short sleep I awoke by a kind of inner explosion of all the senses.
> 18.00 h: an unexpected visit forced me to become active, but during the whole evening I lived more in an inner than in the outer world.
> 22.00 h: all effects worn off, normal feeling.

This was an experiment performed without attention to "set and setting" but it proves that ergonovine possesses a psychotropic, mood-changing, slightly hallucinogenic activity when taken in the same amount as is an effective dose of lysergic acid amide, the main constituent of *ololiuhqui*. Its potency is about one-twentieth of the potency of LSD and about five times that of psilocybin.

There is a further finding that may prove to be of utmost importance in considering Wasson's question. The main constituents of the Mexican morning-glory seeds are (a) lysergic acid amide (= "ergine"), and (b) lysergic acid hydroxyethylamide, and these are also the main alkaloids in ergot growing on the wild grass *Paspalum distichum* L. This grass grows commonly all around the Mediterranean basin and is often infected with *Claviceps paspali*. F. Arcamone *et al.*[3] were the first to discover these alkaloids in ergot of *P. distichum*, in 1960.

Within the kinds of ergot produced by the various species of the genus *Claviceps* and its many hosts, cereals and wild grasses, types of ergot do exist that contain hallucinogenic alkaloids, the same alkaloids as in the Mexican hallucinogenic morning-glories. These alkaloids, mainly lysergic acid amide, lysergic acid hydroxyethylamide, and ergonovine, are soluble in water, in contrast to the non-hallucinogenic medicinally useful alkaloids of the ergotamine and ergotoxine type. With the techniques and equipment available in antiquity it was therefore easy to prepare an hallucinogenic extract from suitable kinds of ergot.

What suitable kinds of ergot were accessible to the ancient Greeks? No rye grew there, but wheat and barley did and *Claviceps purpurea* flourishes on both. We analyzed ergot of wheat and ergot of barley in our laboratory and they were found to contain basically the same alkaloids as ergot of rye, viz alkaloids of the ergotamine and ergotoxine group, ergonovine, and sometimes also traces of lysergic acid amide. As I said before, ergonovine and lysergic acid amide, both psychoactive, are soluble in water whereas the other alkaloids are not. As we all know, ergot differs in its chemical constituents according to its host grass and according to geography. We have no way to tell what the chemistry was of the ergot of barley or wheat raised on the Rarian plain in the 2nd millennium B.C. But it is certainly not pulling a long bow to assume that the barley grown there was host to an ergot containing, perhaps among others, the soluble hallucinogenic alkaloids. The famous Rarian plain was adjacent to Eleusis. Indeed this may well have led to the choice of Eleusis for Demeter's temple, and for the growth of the cluster of powerful myths surrounding them and Triptolemus that still exert their spell on us today.

The separation of the hallucinogenic agents by simple water solution from the non-soluble ergotamine and ergotoxine alkaloids was well within the range of possibilities open to Early Man in Greece. An easier method still would have been to have recourse to some kind of ergot like that growing on the grass *Paspalum distichum*, which contains only alkaloids that are hallucinogenic and which could even have been used directly in powder form. As I said before, *P. distichum* grows everywhere around the Mediterranean basin. During the many centuries when the Eleusinian Mysteries were thriving and holding the antique Greek world enthralled, may not the hierophants of Eleusis have been broadening their knowledge and improving their skills? For the Greek world as for us, the Mysteries are linked to Demeter and Kore, and they and Triptolemus are the famed mythical progenitors of cultivated wheat and barley. But in the course of time the hierophants could easily have discovered *Claviceps paspali* growing on the grass *Paspalum distichum*. Here they would be able to get their hallucinogen direct, straight and pure. But I mention this only as a possibility or a likelihood, and not because we need *P. distichum* to answer Wasson's question.

Finally we must also discuss an ergot parasitical to a wild grass called in scientific nomenclature *Lolium temulentum* L. In English this is most widely known as darnel or cockle or (in the Bible) tares, a weed that plagues grain crops. It is sometimes called "wild rye grass", an unfortunate name because wild rye has nothing to do with rye: the rye of "wild rye grass" is of utterly different etymology. In classic Greek darnel was *aira* and in classic Latin was *lolium*. Its name in French is *ivraie* and in German *Taumellolch*, both names pointing to a belief in its psychotropic activity in the folk knowledge of the traditional European herbalists. A citation for *ivraie* in A. D. 1236 has been found, and it must go back much further than that.

Analysis of *Lolium temulentum* in my laboratory and an extended botanical, chemical, and pharmacological investigation by I. Katz[4] showed that the plant itself contains no alkaloids nor does it possess any pharmacological activity. But the Lolium species (*L. temulentum* and *L. perenne*) are notoriously prey to the Claviceps fungus. The psychotropic reputation of darnel must therefore be attributed to its parasitic infection by ergot. Samples of ergot grown on *L. temulentum* and *L. perenne* collected in Germany, France, and Switzerland showed large variation in their alkaloidal composition. Some contained substantial amounts of ergonovine together with alkaloids of the ergotamine and ergotoxine group.[5] A species of ergot growing on darnel may have existed in ancient Greece that contained mainly hallucinogenic alkaloids of ergot such as we have found in ergot of Paspalum.

In conclusion I now answer Wasson's question. The answer is yes, Early Man in ancient Greece could have arrived at an hallucinogen from ergot. He might have done this from ergot growing on wheat or barley. An easier way would have been to use the ergot growing on the common wild grass Paspalum. This is based on the assumption that the herbalists of ancient Greece were as intelligent and resourceful as the herbalists of pre-Conquest Mexico.

III. Solving the Eleusinian Mystery

by Carl A. P. Ruck

We are told that there once was a young Athenian who was much taken with the beauty of a courtesan in one of the brothels of Corinth. His attempts to repay her favors in some special way were continually frustrated by the madam, who insisted upon confiscating all private gifts. To give the girl something that would be hers alone, he hit upon the idea of offering her an immaterial, and thereby inalienable, benefit: he would pay the expenses for her introduction into the blessed community of those who had witnessed the secret religious ceremony practiced at the village of Eleusis. That sight was generally considered the culminating experience of a lifetime. And so she was allowed to travel to Athens, together with the madam and a younger girl from the brothel. The lover lodged them all with a friend while they prepared themselves by the preliminary rites. The full sequence would require more than half a year's residence in Athens. Then at last, amidst the throng of thousands who each autumn for the first and only time made the pilgrimage, they too walked the Sacred Road, crossing the narrow bridge that still today can be seen, now submerged in the brackish waters of the swamp that once divided Athens from the territory of its neighboring village, some fourteen miles distant, a region sacred for its special affinity with the realm of departed spirits, who were thought to insure the fertility of the adjacent plain of grain. The procession of pilgrims symbolically passed the frontier between worlds, a momentous journey characterized by its difficulty, for the bridge was expressly constructed too narrow for vehicular traffic and ahead, just as they arrived at the village itself, it was traditional that they would be obscenely insulted by masked men, who lined the bridge across the final boundary of water.

Each year new candidates for initiation would walk that Sacred Road, people of all classes, emperors and prostitutes, slaves and freemen, an annual celebration that was to last for upwards of a millennium and a half, until the pagan religion finally succumbed to the intense hatred and rivalry of a newer sect, the recently legitimized Christians in the fourth century of our era. The only requirement, beyond a knowledge of the Greek language, was the price of the sacrificial pig and the fees of the various priests and guides, a little more than a month's wages, plus the expense of the stay in Athens.

Every step of the way recalled some aspect of an ancient myth that told how the Earth Mother, the goddess Demeter, had lost her only daughter, the maiden Persephone, abducted as she gathered flowers by her bridegroom, who was Hades or the lord of death. The pilgrims called upon Iakchos as they walked. It was he who was thought to lead them on their way: through him, they would summon back the queen Persephone into the realm of the living. When at last they arrived at Eleusis, they danced far into the night beside the well where originally the mother had mourned for her lost Persephone. As they danced in honor of those sacred two goddesses and of their mysterious consort Dionysus, the god of inebriants, the stars and the moon and the daughters of Ocean would seem to join in their exultation. Then they passed through the gates of the fortress walls, beyond which, shielded from profane view, was enacted the great Mystery of Eleusis.

It was called a mystery because no one, under pain of death, could reveal what happened within the sanctuary. My colleagues and I, working from hints in numerous sources, have ventured to go beyond that forbidden gate.

Ancient writers unanimously indicate that something was seen in the great *telesterion* or initiation hall within the sanctuary. To say so much was not prohibited. The experience was a vision whereby the pilgrim became someone who saw, an *epoptes.*

The hall, however, as can now be reconstructed from archaeological remains, was totally unsuited for theatrical performances; nor do the epigraphically extant account books for the sanctuary record any expenditures for actors or stage apparatus. What was witnessed there was no play by actors, but *phasmata*, ghostly apparitions, in particular, the spirit of Persephone herself, returned from the dead with her new-born son, conceived in the land of death. The Greeks were sophisticated about drama and it is highly unlikely that they could have been duped by some kind of theatrical trick, especially since it is people as intelligent as the poet Pindar and the tragedian Sophocles who have testified to the overwhelming value of what was seen at Eleusis.

There were physical symptoms, moreover, that accompanied the vision: fear and a trembling in the limbs, vertigo, nausea, and a cold sweat. Then there came the vision, a sight amidst an aura of brilliant light that suddenly flickered through the darkened chamber. Eyes had never before seen the like, and apart from the formal prohibition against telling of what had happened, the experience itself was incommunicable, for there are no words adequate to the task. Even a poet could only say that he had seen the beginning and the end of life and known that they were one, something given by god. The division between earth and sky melted into a pillar of light.

These are the symptomatic reactions not to a drama or ceremony, but to a mystical vision; and since the sight could be offered to thousands of initiates each year dependably upon schedule, it seems obvious that an hallucinogen must have induced it. We are confirmed in this conclusion by two further observations: a special potion, as we know, was drunk prior to the visual experience; and secondly, a notorious scandal was uncovered in the classical age, when it was discovered that numerous aristocratic Athenians had begun celebrating the Mystery at home with groups of drunken guests at dinner parties.

To identify the Eleusinian drug, we must first find the pattern of meaning that underlies the Mystery. The sacred myth that narrates the events involved in the founding of the Mystery is recorded in the so-called Homeric hymn to Demeter, an anonymous poem dating from the seventh century B.C., seven centuries later than the probable date of the first performance of the ceremony. In it we are told how the goddess Persephone was abducted by her bridegroom Hades to the realm of the dead when she picked a special hundred-headed *narkissos* while gathering flowers with the daughters of Ocean in a place called Nysa. All Greek words ending in *-issos* derive from the language spoken by the agrarian cultures dwelling in the Greek lands before the coming of the migrating Indo-European Greeks. The Greeks themselves, however, thought that the *narkissos* was so-named because of its narcotic properties, obviously because that was the essential nature or symbolism of Persephone's flower. The marital abduction or seizure of maidens while gathering flowers is, moreover, a common theme in Greek myths and Plato records a rationalized version of such stories in which the companion of the seized maiden is named Pharmaceia or, as the name means, the "use of drugs". The particular myth that Plato is rationalizing is in fact one that traced the descent of the priesthood at Eleusis. There can be no doubt that Persephone's abduction was a drug-induced seizure.

That fact has never been noticed by Classicists, despite its absolute expectability in terms of what we know about the religions of the agrarian peoples who preceded the Greeks. Those religions centered upon the female's procreativity and the cyclical rebirth and death of both plants and mankind. She was the Great Mother and the entire world was her Child. The essential event in those religions was the Sacred Marriage, in which the priestess periodically communed with the realm of spirits within the earth to renew the agricultural year and the civilized life that grew upon the earth. Her male consort was a vegetative spirit, both her son who grew from the earth and the mate who would abduct her to the fecundating other realm as he possessed her upon his death. When the roving Indo-Europeans settled in the Greek lands, their immortal Father God of the sky, who was Zeus, became assimilated to the pattern of the dying and reborn vegetative consort of the Great Mother. There are indications of this assimilation in the traditions about the Zeus who was born and died in Crete. Furthermore, archaeological remains from the Minoan-Mycenaean period of Greek culture frequently depict visionary experience encountered by women engaged in rituals involving flowers. The priestesses or goddesses themselves occur as idols decorated with vegetative motifs, accompanied by their serpent consort or crowned with a diadem of opium capsules. Moreover, the myths that narrate the founding of the various Mycenean citadels show, as we might expect, recurrent variations upon the Sacred Marriage enacted between the immigrant founder and the autochthonous female in ecstatic contexts. Most interesting among these are the traditions about Mykenai (Mycenae) itself, for it was said to have been founded when the female of that place lost her head to the male of the new dynasty, who had picked a mushroom. The etymology of Mykenai, which was recognized in antiquity but has been repeatedly rejected by modern scholars, is correctly derived from Mykene, the bride of the *mykes* or mushroom. Fungoid manifestations of the vegetative consort in the Sacred Marriage can also be detected in the symbolism of the founding fathers at other Mycenaean sites, perhaps because that particular wave of immigrants brought knowledge of the wild and untameable mushroom with them on their movement south into the Greek lands. At Athens in the classical period, the ancient Sacred Marriage was still celebrated annually by the wife of the sacral head of state: in the month of February, she would unite with the god Dionysus.

It was as Dionysus that the Zeus who had been assimilated as consort to the Mother Goddess survived into the classical period. His name designates him as the Zeus of Nysa, for Dios is a form of the word Zeus. Nysa was not only, as we have seen, the place where Persephone was abducted, but also the name for wherever was enacted that same nuptial encounter involving the passion of Dionysus' birth and death. When he possessed his women devotees, the maenads or bacchants, he was synonymous with Hades, the lord of death and bridegroom to the goddess Persephone. The maenads, like Persephone, also gathered flowers. We know this because their emblem was the *thyrsos*, a fennel stalk stuffed with ivy leaves; such hollow stalks were customarily used by herb gatherers as receptacles for their cuttings, and the ivy that was stuffed into the maenads' stalks was sacred to Dionysus and reputed to be a psychotropic plant.

Dionysus, however, could possess his ecstatic brides through the agency of other plants as well, for he was the vegetative consort residing in all manner of inebriants, including apparently certain of the fungi. The stipe, by analogy to the maenads' emblem, was also called a *thyrsos*, with the mushroom's cap substituted for the psychotropic herbs. Dionysus himself was born prematurely in the mystical seventh month during a winter snowfall when his celestial father struck his earth bride Semele at Thebes with a bolt of lightning; in the same manner mushrooms were thought to be engendered wherever lightning struck the earth. The father of Dionysus was another Dionysus, as would be expected in a Sacred Marriage, for the child born at the time of the earth's renewal is identical with the ingested consort who will reunite his mother-bride with the awesome nether realm from which life must forever be reborn. Thus not surprisingly we are told that Semele also conceived Dionysus when she drank a potion compounded of her own son's heart. So too was Dionysus like his father also called the thunderer, for despite the gentleness of his infancy and his sometimes effeminate appearance, he could suddenly metamorphose into the virulence of his full manhood, in which form he was a bull, rending the earth, as at his birth, announced by a bellowing, the mykema that signified the presence of the *mykes* or mushroom. His symbol was the phallos itself, by a common metaphor also called the *mykes.*

It was with the vine, however, and its fermented juice that Dionysus was chiefly associated. Mushrooms themselves in fact were considered a fermentation of the earth, a perfect symbol of rebirth from the cold realm of putrefaction that was the mouldy other world. A similar process was sensed in the frothing turmoil whereby the fungal yeast converted grapes into wine. In wine the god had found his greatest blessing for mankind; here his untameable, wild nature had succumbed to domestication. He himself was said to have first discovered the properties of this plant that had grown from the spilled blood of the gods when he noticed a serpent drinking its toxin from the fruit, for serpents were thought to derive their poisons from the herbs they ate, just as conversely it was said that serpents could transfer their toxins to plants in their vicinity. Dionysus taught man the way to calm this gift's violent nature by diluting it with water. And customarily it was mixed with water that the Greeks drank their wines.

This custom of diluting wine deserves our attention since the Greeks did not know the art of distillation and hence the alcoholic content of their wines could not have exceeded about fourteen percent, at which concentration the alcohol from natural fermentation becomes fatal to the fungus that produced it, thereby terminating the process. Simple evaporation without distillation could not increase the alcoholic content since alcohol, which has a lower boiling point than water, will merely escape to the air, leaving the final product weaker instead of more concentrated. Alcohol in fact was never isolated as the toxin in wine and there is no word for it in ancient Greek. Hence the dilution of wine, usually with at least three parts of water, could be expected to produce a drink of slight inebriating properties.

That, however, was not the case. The word for drunkenness in Greek designates a state of raving madness. We hear of some wines so strong that they could be diluted with twenty parts of water and that required at least eight parts water to be drunk safely, for, according to report, the drinking of certain wines straight actually caused permanent brain damage and in some cases even death. Just three small cups of diluted wine were enough in fact to bring the drinker to the threshold of madness. Obviously the alcohol could not have been the cause of these extreme reactions. We can also document the fact that different wines were capable of inducing different physical symptoms, ranging from slumber to insomnia and hallucinations.

The solution to this apparent contradiction is simply that ancient wine, like the wine of most early peoples, did not contain alcohol as its sole inebriant but was ordinarily a variable infusion of herbal toxins in a vinous liquid. Unguents, spices, and herbs, all with recognized psychotropic properties, could be added to the wine at the ceremony of its dilution with water. A description of such a ceremony occurs in Homer's *Odyssey*, where Helen prepares a special wine by adding the euphoric *nepenthes* to the wine that she serves her husband and his guest. The fact is that the Greeks had devised a spectrum of ingredients for their drinks, each with is own properties.

Thus the wine of Dionysus was the principle medium whereby the classical Greeks continued to partake of the ancient ecstasy resident in all the vegetative forms that were the Earth's child. In social situations, the drinking was regulated by a leader, who determined the degree of inebriation that he would impose upon the revelers as they ceremonially drank a measured sequence of toasts. At sacral events, the wine would be more potent and the express purpose of the drinking was to induce that deeper drunkenness in which the presence of the deity could be felt.

The herbal inebriants that figured in these Dionysian rites of drinking required magical procedures when the herbs were gathered. As wild beings whose spirits were akin to their particular guardian animals, the plants were the objects of a hunt. And the ecstatic rapture they might induce in religious contexts inevitably identified them as sexual forces.

Thus the female devotees of the god Dionysus appropriately bore the *thyrsos* as their emblem as they roamed the winter mountainsides in search of the so-called vine that grew suddenly with earth-rending thunder and the bellowing of bulls amidst their night-long dancing; that beloved child, the age-old serpent consort, was the object of their hunt, who was suckled, then like a beast torn to pieces and eaten raw; his own mothers, as was often claimed, were guilty of cannibalism eating his flesh, for like mothers the women would have brought the drug into being, harvesting and compounding it with the help of the god's so-called nurses, in whose loving care he would grow to manhood, eventually to possess them as his brides. Such ceremonies enacted the sacred nuptials of the city's women, who thereby entered the awesome alliance with the nether lord, upon whose realm depended the growth of all this world's fertility of plants and man.

Persephone's abduction at Nysa was prototypic of that first nuptial between the realms, the primal experience of death. In the hunting place called Agrai, in the month of February, which was called the time of flowers, the candidates for the coming initiation at Eleusis experienced in some way the death of Persephone through the ritual mimeses of those Dionysian events. That occurrence was termed the Lesser Mystery and it was considered a preliminary for the vision of the Greater Mystery that would take place at the time of the autumn sowing in September.

The Greater Mystery was the complement of the Lesser, for it centered upon redemption instead of death, the triumphant return of Persephone from Hades with the infant son she had conceived during her sojourn in communion with the spiritual realm. The Homeric hymn, after its account of Persephone's fatal nuptial encounter, goes on to tell how Demeter came to establish the Greater Mystery. In grief for her lost daughter, she went to Eleusis. Her journey there is a sympathetic imitation of Persephone's entrance into the citadel of Hades, for Eleusis was a simulacrum of the other word, where Demeter too would experience the ominous chthonic phase of her womanhood, not as sacred queen to the lord of death, but as witch and wet-nurse in his house, for when Persephone progresses beyond maidenhood, her mother must make way, relinquishing her former role and moving on to the third stage, when a woman's aging womb brings her once again into proximity with the powers of death. These chthonic or earth-oriented phases of womanhood were symbolized in the goddess Hecate, whose triform body expressed the female's totality as bride, wife, and aged nurse in Hades' realm.

At Eleusis, Demeter first attempts to assuage her grief by negating the possibility of the world of death to which she has lost her daughter. She does this by nourishing the royal prince with immortality. His mother, however, objects, for she cannot understand or accept a system that would inevitably alienate the son from his own mother's realm as irredeemably as Persephone from Demeter.

Demeter again attempts a solution, this time an eternity of death, in which she and the maiden would stay forever in their chthonic phase. She causes a plague of sterility so that no life can emerge from the earth. This solution, however, leaves no role for the immortal deities of the sky, whose delicate balance with the forces of the earth is dependent upon the continuing worship of mortal men, who share with them the fruits of life.

The final solution is to heal the universe into which death has now intruded by admitting also the possibility of return into life. Rebirth from death was the secret of Eleusis. In Hades, Persephone, like the earth itself, takes seed into her body and thereby eternally comes back to her ecstatic mother with her new son, only to die as eternally in his fecundating embrace. The sign of the redemption was an ear of barley, the risen grain, that following the Mystery would be committed once again to the cold earth in the sowing of the sacred plain adjacent to Eleusis.

This was the final mediation that Demeter taught to a second of the royal princes in the citadel of Eleusis. His name was Triptolemus, the trifold warrior, and he becomes the apostle of the new faith, traveling throughout the world on a serpent chariot spreading the gospel of the cultivation of grain. His exact identity was part of the secret of the Mystery, for the various traditions about his parentage suggest that the initiates learned that, like the grain that was his emblem, he was actually the son of the trifold females who were the queens in the house of the lord of death. He was, therefore, another form of Dionysus, who in a similar fashion also was an apostle, traveling in the same manner of cart on his journey teaching man the cultivation of the vine. The pattern indicated in these Eleusinian apostleships clearly signifies the transition from wild botanic growth to the arts of cultivation upon which civilized life must depend.

In the various Eleusinian mythical traditions, several other male figures symbolize a similar transmutation of the wild horror and loss that is death into the ravishingly handsome young man who is born from Hades' realm in pledge of the coming redemption. In one such tradition, he is Iakchos (Iacchus), the joyous Dionysian male who led the initiates toward their vision of salvation; in another, Eubuleus, the serene personification of the cosmological plan wherein the celestial immortals collaborated with the forces of death to show humankind its proper role; in a third, Zagreus, the enigmatic hunting companion of his ecstatic brides. The fourth and most perfect of these transmuted figures is Ploutos, the personification of the wealth that stems from the fertility of man and field. The initiate could expect that this beneficent representative of death would thereafter become welcome in his house as his constant guest, joined by ties of friendship. This Ploutos was originally the vegetative son of Demeter in her more ancient days as Great Mother on Crete, where she conceived him in a thrice plowed field when she united with her intoxicating mate whose name was Iasion, which means "the man of the drug".

Triptolemus, however, was the paramount transmutation, Demeter's special response to the problem of death. It was his sacred barley, solemnly grown in the Rarian plain and threshed on his floor, that was the principle ingredient in the potion drunk by the initiates in preparation for the culminating vision. The formula for that potion is recorded in the Homeric hymn. In addition to the barley, it contained water and a fragrant mint called blechon. The mint initially would seem the most likely candidate for the psychoactive agent in the potion, except that all our evidence about this particular mint indicates that it was unsuitable, being neither sufficiently psychotropic to warrant the danger of profane usage nor appropriately revered as the secret drug. Rather, it was openly despised as a sign of the illicit union of man and woman in lustful concubinage without the sacrament of marriage. To just such an unsanctified abduction Demeter had lost her daughter at Nysa and accordingly we are told that the mother vented her displeasure by changing the prostitute of Hades into mint, thereupon grinding and bruising her botanic body. The final Eleusinian solution, on the other hand, will reconcile the mother to the daughter's loss through legitimatizing the nuptial abduction in the rite of matrimony, whereby an heir can accede to the dynastic house. Barley and not mint is the revelation at Eleusis, and it is to it that we must look for the sacred drug.

With the cultivation of grain, man had left his wild, nomadic ways and settled in cities, giving to the earth in order to receive back its harvest. All civilized institutions derived from this delicate accord struck with the dark, cold forces of death. Grain itself was thought to be a hybrid, carefully evolved from more primitive grasses. If not tended with proper care, it could be expected to revert to its worthless, inedible avatar. That primitive sibling to grain was thought to be the plant called *aira* in Greek, *Lolium temulentum* in botanical nomenclature, or commonly in English wild ryes, darned cockle, ivray, or finally "tares" in the Bible. This weed is usually infested with a fungoid growth, *Claviceps purpurea*, ergot or rust, a reddening corruption to which barley was thought to be particularly susceptible. *Aira*, therefore, doubly endangered the cultivated staff of life, first as the renascent primordial grass and secondly as the host for the encroaching ergot infection. The revertive tendency of the infected grain, furthermore, was all too obvious, for when the sclerotia fell to the ground there grew from them not grain but tiny purple mushrooms, the fruiting bodies of the ergot fungus, clearly a return to the species of the unregenerate, wild Dionysian abductor.

Unlike the seedless mushroom, however, ergot would have seemed akin to the kernels of grain that were its host. As well as grain, therefore, it too was Demeter's plant, for she could wear its distinctive color as her robe or on her feet or be named with its epithet, Erysibe. The hallucinogenic properties of *Claviceps* were recognized in antiquity, and thus we may surmise that the parallel apostleships of the barley and the vine would have signified analogous transmutations wherein the chthonic spirits submitted to cultivation. Wine, however, was Dionysus' realm, the liquid that gave sleep like death and forgetfulness, whereas Demeter was the earth, dry with the harvest upon which man fed to live. Grain was her sacrament. Upon first coming to Eleusis, Demeter had refused the cup of wine and the initiates thereafter imitated her abstention in deference to the superior symbolism of the potion of barley.

Clearly ergot of barley is the likely psychotropic ingredient in the Eleusinian potion. Its seeming symbiotic relationship to the barley signified an appropriate expropriation and transmutation of the Dionysian spirit to which the grain, Demeter's daughter, was lost in the nuptial embrace with earth. Grain and ergot together, moreover, were joined in a bisexual union as siblings, bearing at the time of the maiden's loss already the potential for her own return and for the birth of the phalloid son that would grow from her body. A similar hermaphroditism occurs in the mythical traditions about the grotesquely fertile woman whose obscene jests were said to have cheered Demeter from her grief just before she drank the potion.

This solution to the Mystery of Eleusis is made still more probable by a papyrus fragment that was brought to my attention by our translator of the Homeric hymn. The fragment preserves a portion of the *Demes*, a comedy by Eupolis written shortly after the scandal of the profanation of the Mystery in the fifth century B.C. It confirms that the profanation did indeed entail the drinking of the sacred *kykeon* and suggests that our identification of the drug it contained is correct. In the comedy, an informer explains to a judge how he had come upon someone who had obviously been drinking the potion since he had barley groats on his moustache. The accused had bribed the informer to say that it was simply porridge and not the potion that he had drunk. By a possible pun, the comedian may even indicate that the incriminating "crumbs of barley" were "purples of barley".

Thus we may now venture past the forbidden gates and reconstruct the scene within the great initiation hall at Eleusis. The preparation of the potion was the central event. With elaborate pageantry, the hierophant, the priest who traced his descent back to the first performance of the Mystery, removed the sclerotia of ergot from the free-standing room constructed inside the *telesterion* over the remains of the original temple that had stood there in Mycenaean times. As he performed the service, he intoned ancient chants in a falsetto voice, for his role in the Mystery was asexual, a male who had sacrificed his gender to the Great Goddess. He conveyed the grain in chalices to the priestesses, who then danced throughout the hall, balancing the vessels and lamps upon their heads. The grain was next mixed with mint and water in urns, from which the sacred potion was then ladled into the special cups for the initiates to drink their share. Finally, in acknowledgment of their readiness, they all chanted that they had drunk the potion and had handled the secret objects that had come with them on the Sacred Road in sealed baskets. Then, seated on the tiers of steps that lined the walls of the cavernous hall, in darkness they waited. From the potion they gradually entered into ecstasy. You must remember that this potion - an hallucinogen - under the right set and setting, disturbs man's inner ear and trips astonishing ventriloquistic effects. We can rest assured that the hierophants, with generations of experience, knew all the secrets of set and setting. I am sure that there was music, probably both vocal and instrumental, not loud but with authority, coming from hither and yon, now from the depths of the earth, now from outside, now a mere whisper infiltrating the ear, flitting from place to place unaccountably. The hierophants may well have known the art of releasing into the air various perfumes in succession, and they must have contrived the music for a crescendo of expectation, until suddenly the inner chamber was flung open and spirits of light entered the room, subdued lights I think, not blinding, and among them the spirit of Persephone with her new-born son just returned from Hades. She would arrive just as the hierophant raised his voice in ancient measures reserved for the Mystery: "The Terrible Queen has given birth to her son, the Terrible One". This divine birth of the Lord of the Nether World was accompanied by the bellowing roar of a gong-like instrument that outdid, for the ecstatic audience, the mightiest thunderclap, coming from the bowels of the earth.

Some Christian bishops, in the last days of the Mystery, thought they had discovered and could reveal the secret of Eleusis. One said that in this pagan rite there was materialized a stalk of barley. How true according to his limited lights, yet how utterly false. The Bishop had not known the night of nights at Eleusis. He was like one who has not known LSD or the mushrooms of Mexico or the morning-glory seeds. For close on to two thousand years a few of the ancient Greeks passed each year through the portals of Eleusis. There they celebrated the divine gift to mankind of the cultivated grain and they were also initiated into the awe some powers of the nether world through the purple dark of the grain's sibling that Dr Hofmann has once again made accessible to our generation. The myths of Demeter and Persephone and all their company fit our explanation in every respect. Nothing in any of them is incompatible with our thesis.

Until yesterday we knew of Eleusis only what little a few of the initiates told us but the spell of their words had held generations of mankind enthralled. Now, thanks to Dr Hofmann and Gordon Wasson, those of us who have experienced the superior hallucinogens may join the fellowship of the ancient initiates in a lasting bond of friendship, a friendship born of a shared experience of a reality deeper far than we had known before.

IV. Ancillary Data

by R. Gordon Wasson, Albert Hofmann, and Carl A. P. Ruck

A Greek scholar, writing just half a century ago, did not hesitate to dismiss the worship of Demeter at Eleusis as "trivial and absurd; but," he added, "there can be no doubt that it did much to satisfy the emotional side of the religious instincts of the Greeks. Its modern analogue is perhaps the Salvation Army." We trust that our own comparisons will be less bizarre than his. In our generation we enjoy the advantage of having rediscovered the hallucinogenic experience. Moreover, the value of interdisciplinary collaboration is that it gives us access to knowledge otherwise apt to be beyond the reach of scholars. Our joint effort has yielded a radical answer to our problem: it sets the stage for much reexamination of traditional opinions about the classical Greeks and their tragic literature in celebration of the god Dionysus.

The ancient testimony about Eleusis is unanimous and unambiguous. Eleusis was the supreme experience in an initiate's life. It was both physical and mystical: trembling, vertigo, cold sweat, and then a sight that made all previous seeing seem like blindness, a sense of awe and wonder at a brilliance that caused a profound silence since what had just been seen and felt could never be communicated: words are unequal to the task. Those symptoms are unmistakably the experience induced by an hallucinogen. To reach that conclusion, we have only to show that the rational Greeks, and indeed some of the most famous and intelligent amongst them, could experience and enter fully into such irrationality.

Eleusis was different from the convivial inebriation of friends at a *symposion* or the drunken *komos* revel at the festivals of drama. Eleusis was something for which even the maenadic ecstasy of the mountain women was only partial preparation. In their various ways, other Greek cults too enacted aspects of the ancient communion practiced between gods and men, between the living and the dead, but it was at Eleusis alone that the experience occurred with overwhelming finality: here alone was the grand design fulfilled of the maiden resurrected with her son conceived in death, and of the ear of barley that like her had sprouted beneath the earth. By this resurrection was validated the continuance of all that a Greek held most dear, the civilized way of life that, beyond each city's constitution, was the Greek heritage, evolved out of aboriginal primitivism just as all life too came from the beneficent accord with the lord of death. Here indeed is a rich full-bodied myth, filled with contradictions like all the myths of an unlettered age, one saying this and another saying that and a third saying something else, but somehow in the end harmonizing into one whole, a myth that for the Greeks explained the beginning and the end of things.

Months of learning and rituals preceded the revelation on the Mystery night, each action programming in further detail the meaning and substance, the full ramifications of the vision that lay ahead. At last the initiates would sit on the steps in the initiation hall. It was all done now except for the finale. They had learned the secret version of the sacred myth, they had bathed in the sea, abstained from various tabu foods and drinks, sacrificed a pig, taken the long walk along the Sacred Way from Athens, and made the perilous crossing of the final division of water before their arrival at the city of their Eleusinian hosts. Outside the sanctuary walls, there was the night-long dance beside the Maiden's Well on the very ground that the goddess had visited. Then there was the fast and the momentous entrance into the forbidden territory past the cave that was an entrance to Hades and the rock where Demeter had sat in grief. In the initiation hall, there was the final ceremonial dance of the priestesses carrying the chalice of grain upon their heads as they mixed and distributed the sacred potion: fragrant *blechon*, the despised herb associated with the illicit nature of the abduction, immersed in water to which was added a sprinkling of flour from barley grown in the Rarian plain. The barley's potential as the foodstuff for mankind depended upon keeping at bay the encroachment of the reddening corruption that would draw it back to its worthless avatar, the rust-infested weed. Like the *blechon*, the weed too was thus associated with primitivism and the ways of life before the institutions of society brought man to a higher mode of existence. Of these two plants the initiates drank and then paused expectant for redemption while the hierophant chanted the ancient words. Then, suddenly, there was light and the boundaries on this world burst their bounds as spiritual presences were felt in their midst and the hall was flooded with glowing mystery.

From beginning to end here there was a reenactment of a sacred drama in which the initiates as well as the officiants had their role to play, until at last they experienced as actors the ineffable, all of their senses and emotions being shot through with what would thereafter be forever the unspeakable.

As the initiates passed through the lengthy proceedings, they were admitted to many secrets, but the hierophants may well have withheld from them the Secret of Secrets: the sacred water of the potion had already soaked up in the right dosage from the immersed ergot what it contained of ergine and ergonovine, as we call them today. But the hierophants were certainly, through the centuries, seeking ways to improve their technique, their formulae. In the course of those two millennia may they not have discovered a kind of ergot that contains solely the hallucinogenic alkaloids such as has been found in modern times in ergot of *Paspalum distichum*? Indeed herbalists other than the hierophantic families may have shared in this discovery and it may have been their knowledge that prompted the rash of profanations in B.C. 415. The inside story of those events will never be known but that there was a story to tell is certain.

In unlettered cultures the knowledge of the herbalist - the knowledge of the properties of plants and their use - was everywhere a body of secret lore passed on by word of mouth from herbalist to apprentice and sometimes from one herbalist to another. The apprenticeship took years before one practiced on one's own, and one never stopped learning. There were questions of dosage, of side effects, of proper plant ingredients that became poisons when taken to excess. In Mexico Bernardino de Sahagun and Francisco Hernandez were gifted Spaniards and they spent endless effort and time to take down from the Indians the virtues of various Mexican plants. But they were Europeans who knew not the American plant world, and in their European world they were certainly not what we would call botanists or herbalists. Their intentions were good but their ignorance was complete. What they have to tell us about the hallucinogens is childish. They could have tried the hallucinogens but elected not to do so, spurned the chance. What a different story they would have told us if they had lived for a number of years as apprentices of the Indian *sabios*.

In the Homeric hymn to Demeter, on arriving at Eleusis, tired and disconsolate over the loss of her daughter Persephone, Demeter was offered a drink of wine, which she declined. Since every act in this narrative had mythic meaning, it seems that drinking the alcoholic beverage did not go with the drinking of the divine potion called kykeon. The two kinds of inebriation were incompatible. In Mexico those who will take the mushrooms know that they must refrain from drinking alcoholic beverages for four days before the *velada*, as the mushroom celebration is called. Alcoholic inebriation would profane, would defile, the divine draught, alike in Mexico and Greece.

The Eleusinian Mysteries were in the exclusive hands of the Eumolpus and Kerykes families. For close to two thousand years, these hierophants governed with autocratic authority the rites at Eleusis. By contrast, in the sacred mushroom country of Mexico every village has its *sabios* ("wisemen") who are the custodians of the rite. (In some remote Mixe villages the individual families take the mushrooms when they feel the need, without the guidance of a sabio. Whether this informal practice in the Mixe country marks a breakdown in the rite or the survival of an earlier archaic procedure, we do not know.) In Greece the "initiate" took the potion only once in his life, and thus he could not compare successive experiencies. In Mexico one may consult the mushroom whenever a grave family problem presents itself. Some Indians choose never to take the mushroom, others only once, yet others intermittently. The newcomer to the experience is constantly warned that ingesting the hallucinogen is in the highest degree *delicado*, "delicate" with a connotation of grave danger.

At Eleusis and in Mexico certain items of food were proscribed for some time before the big night. It is impossible to compare the dietary exclusions, so different are the foods, except that in both cases eggs are tabu. Fasting was practiced in Greece and also in Mexico, from the morning throughout the day: in both cases one faced the night on an empty stomach. In Mexico before the Conquest it was the practice in aristocratic circles to drink nourishing chocolate spiked with the inebriating mushrooms, in this way breaking the fast as the events of the night were launched on their course. Owing to the silence enjoined on everyone who had taken part in the Mystery, there are scarcely any hints as to what happened in the writers of the flourishing period of Eleusis, but in the early centuries of the Christian era, with Eleusis breaking down, we discover a few references, obscure, inhibited, that may permit us some uncertain glimpses. We find mention of a collation served to the initiates when a large cake called the *pelanos*, made of barley and wheat harvested in the adjacent sacred Rarian plain, was broken into pieces and the portions served to all. In the sources one hears of a bond of alliance and friendship that sprang up among the initiates, and some have suggested that this sprang from the collation they had shared together. It is not incompatible with the Greek texts to suppose that the collation paralleled the breaking of the fast in Mexico, the *pelanos* taking the place of the chocolate. But surely the bond of alliance and friendship had nothing to do with the collation: nothing so jejune would have sufficed. The overwhelming effect of the night under the influence of an hallucinogen gives natural birth to a feeling of shared supernatural experience never to be forgotten, a feeling of *cofradia*, of brotherhood. Two of us have known this personally in Mexico: those who pass through a *velada*, in the right set and setting, live through an awesome experience, and feel welling up within them a tie that unites them with their companions of that night of nights that will last for as long as they live. Here we think is the bond of alliance and friendship of which the Greek sources speak obscurely.

Then there is the matter of secrecy. In Mexico nothing had been heard of the sacred mushrooms in sophisticated circles since the early friars mentioned them briefly in the sixteenth and seventeenth centuries. It has been said that the mushrooms were a "secret" of the Indians living in the highlands of southern Mexico. Our own little group flushed them out into the open. But we think this "secret" was never really a secret. In the Indian communities everyone knew about them and also about the morning-glory seeds. Every villager could, if he wished, learn the art of recognizing the sacred mushrooms and many did so. There was a small trade in the mushrooms, supplying the demand among the natives who had moved to the cities and who still wished to "consult" them. The Church had originally opposed them and the Holy Office of the Inquisition in the sixteenth and seventeenth centuries tried to stamp out the native use of them by vigorous persecutions. They failed, of course, but the natural mycophobia of the Spanish population, their contempt for peculiar native practices, and the similar attitude of the French, the Germans, and the English who later came to know Mexico led naturally to an absence of communication between the natives and the occupying races on matters that lay closest to the Indians' hearts. It is small wonder that the sacred mushrooms, after an abortive spate of notices, hopelessly inadequate, in the writings of the early friars, have remained unknown to the world to our own times. The Indians would not take the initiative in speaking about them. The "secrecy" was not a conspiracy of silence: it was imposed on the Indians by the White Man, owing to the lack of intelligent and sympathetic curiosity in the elite of the White circles.

The secrecy in the ancient Greek world about the Eleusinian Mysteries was somewhat different. The laws of Athens made it a crime to speak about what went on at Eleusis in the telesterion. Toward the end of the Homeric hymn to Demeter, this silence is expressly enjoined on all initiates. In B.C. 415 there was a spate of deliberate profanations of the Mysteries by the jet set in Athens and a crackdown followed, harsh penalties being inflicted. But the secrecy ran far beyond the reach of the laws of Athens. That secrecy ruled everywhere in the Greek world and was never seriously violated. It too was self-enforcing. Those who knew the superior hallucinogens through personal experience were not inclined to discuss with outsiders what was revealed to them: words could not convey to strangers the wonders of that night and there would always be the danger that the effort to explain would be met with incredulity, with the scoffing and mockery that would seem to the initiate sacrilegious, would wound him in the very core of his being. One who has known the ineffable is loath to embark on explanations: words are useless.

So far as we can say, at every point what happened at Eleusis fits in with the hallucinogenic experience in Mexico but in one major respect the Mexican rite outdistances Eleusis. They both share in the great Vision ("Vision" embracing all the senses and the emotions), but in Mexico the sacred mushrooms (and the other superior hallucinogens) serve also as oracles. The hierophants of Eleusis saw a new crop of initiates every year and there were many initiates. With the limitations that this procedure imposed, they could not serve as consultants either to individuals or the State on grave problems where these would be needing advice. In Mexico, on the other hand, the hallucinogen is consulted from time to time on all kinds of serious matters. The questions put to the mushrooms must be serious: if they are unworthy or frivolous, the suppliant is in for a sharp rebuff. Faith in the mushrooms among the Indians where traditional beliefs still prevail is absolute. When the suppliant has observed all the tabus, when the *velada* takes place under the right circumstances of darkness and silence, and when he poses his questions with a pure heart, the mushrooms will not lie. So say the Indians. And such meager evidence as one of us has suggests that they may be right.

Toward the end of the last century the world learned of peyotl and early in the middle of this century the hallucinogenic morning-glory seeds were identified by Richard Evans Schultes. A little later the sacred mushrooms of Mexico received their full meed of public attention, located and written up by Roger Heim and one of us. They were shown the way by a botanist, Blas Pablo Reko, and an anthropologist, Robert J. Weitlaner. Now the three of us are submitting to the modern world what well may be the key to the mystery of the Eleusinian Mysteries. The tie that binds the grain of Triptolemus to the supernal experience of Eleusis, easily and safely attainable from ergot, is so close and natural and poetically satisfying, complying point by point with the myth of Demeter and Persephone, that are we not virtually compelled to accept this solution?

Further avenues of inquiry open up. For example, the pregnant empresses of Byzantium lived in a porphyry-lined chamber so that their progeny would be born "in the purple" ("porphyry" = purple). Was this "purple" the color of *Claviceps purpurea* and do we have here a posthumous outcropping of the purple-robed Demeter and Hades-of-the-purple-hair? The earliest codices were written on purple vellum. Was this because only the most exalted color would be fitting, eg, for St. Augustine's *De Civitate Dei*? By a knee-jerk reflex the values of the Pagan world would thus live on under the Christian Dispensation.

V. The Homeric Hymn to Demeter

Let me tell you the story of Demeter, the holy goddess whose hair grew in rich plaits as only a goddess's does, and of her daughter, whom Hades seized. Zeus, the thunder god, gave her to him. This is how it happened.

She was playing far from Demeter, lady of the harvest who reaps with a golden sickle, gathering flowers with the daughters of Ocean, roses and crocus and beautiful violets, iris, hyacinths, and the narcissus. Earth brought forth the narcissus as a wonderful lure for the blossoming girl according to Zeus's plan to please Hades, who receives all. It was an object of awe for all to see, both the immortal gods and mortal men. And from its root grew a hundred heads, smelling a smell so sweet that the whole broad sky above and all the earth laughed and the salty swell of the sea. The girl was amazed and stretched out both her hands to take the marvelous bauble. But as she did, the earth gaped open and Lord Hades, whom we all will meet, burst forth with his immortal horses into the Nysian plain. Lord Hades, the son of Cronus who is called by many names. Begging for pity and fighting him off, she was dragged into his golden chariot. She screamed the shrill cry of a maenad, calling father Zeus, Zeus the highest and the best. But none of the immortals nor any mortal man heard her voice, not even the olive trees that produce splendid fruit; only Hecate, who wears a delicate veil, Persaeus's kindly daughter, heard her from her cave - and Lord Helius, the brilliant son of Hyperion, he too heard the girl's cries to her father. But the son of Cronus was sitting far from the gods in his temple, a temple thronged with worshippers. And as he received sacrifice from mortal men, she was being carried off at his suggestion by his own brother, the one who rules over many and receives all - the son of Cronus who has many names, Hades, and his immortal horses.

As long as the maiden goddess could still see the earth and the starry skies, the sea that ebbs and the rays of the sun, she could still hope to join her beloved mother and the race of the gods who will always be. And that hope consoled her in her misery. The peaks of the mountains resounded with her immortal voice, and the depths of the sea, until at last her mother heard her cries. So bitter was the pain that seized the goddess's heart, that she tore from her head a gossamer veil, the veil that covered her divine hair, and threw over her shoulders a great black cloak, the mantle of death.

She flew swift as a bird over land and sea, seeking her daughter, but no one wanted to tell her the truth, no god nor any mortal man; nor did any bird come to her and we all know birds bear true messages. So for nine days, holy Deo roamed over the earth, carrying blazing torches in her hands, and so great was her grief that she refused the taste of ambrosia and sweet nectar and shunned the bath. But when dawn arrived bearing light for the tenth day, Hecate met her, holding a flame in her hand and bringing her a message - she told her this tale:

> 'Great Demeter, Goddess who brings in the seasons and gives splendid gifts, who of the heavenly gods or mortal men took Persephone and has broken your heart? I have come to you because I heard a cry, but I did not see with my own eyes who took her - here is all I know.'

So said Hecate, but the daughter of Rhea, Demeter whose hair grew in rich plaits as only a goddess's does, did not answer her with words; instead she swiftly flew with her, carrying blazing torches in her hands. They sped straight to Helius, the sun, watchman of the gods and of men, and standing in front of his horses, Demeter, goddess among goddesses, said:

> 'Helius, since we both are gods, you must help me, if ever in word or deed I warmed your heart and soul. I bore a daughter, a beautiful child with beautiful face, whose cries I heard through the uncharted skies, the cries of a captive - although I did not see anything with my own eyes. But you, because you see everything beneath with your divine rays, everything on land and sea, you must tell me the truth. Did you see my child anywhere? Who has taken her from me against her will? Was it a god or some mortal man?'

She said that. And the son of Hyperion answered her by saying:

> 'Lady Demeter, daughter of Rhea whose hair grows in rich plaits as only a goddess's does, you will know the truth, since I stand in awe of you and pity you for how you suffer over the loss of your child. Zeus alone of the immortals is to blame, for he gave her to Hades, his own brother, to

> have for his wife. Seizing her, he led her to the sunless west, and her screams were shrill as a maenad's. But, Goddess, cease your great lament; you need not have such wrath: Aidoneus, the ruler of many, is your own brother and is not an unfitting husband among the immortals for your daughter. As for honor, he has his third of the world that he received when the realms were first apportioned and is the lord over those he received and with whom he dwells.'

When he had said this, he roused his horses and at his bidding they bore the swift chariot easily through the air like long-winged birds. Hearing him, Demeter's grief became anguish and her heart swelled with wrath. Angered with Zeus, the storm-black son of Cronus, she stayed away from the assembly of the gods and lofty Olympus and went in disguise for a long time to dwell with mortal men. No man who saw her knew her nor did any of the women who at that time wore their belts low over their hips, until she arrived at the house of the wise man Celeus, who was at that time the lord of Eleusis, where incense is always burning. She sat broken-hearted near the road at the Virgin's Well, where the women of the town drew water and where a dense olive tree grew giving shade. Sitting there, she looked like a woman long since a crone, who can bear no children nor enjoy the gifts of Aphrodite; such women are nurses for the children of kings, who administer justice, and they work as housekeepers throughout their endless rooms. The daughters of Celeus, son of Eleusinus, saw her as they were bringing bronze jars of water to their father's house. There were four daughters, whose flowering beauty was such beauty as goddesses have: Callidice and Cleisidice, lovely Demo and Callithoe, who was the eldest of them all. They did not recognize the woman as Demeter, however, since it is always difficult for the gods to be seen by mortals. But, standing near her, they said:

> 'Who are you, old woman? Why do you stay outside the town instead of approaching the city? There, in the shadowy halls, there are women as old as you - and younger ones as well - who will welcome you in word and deed.'

That's what they said and lady Demeter answered them:

> 'Dear children, bless you, whoever you are, you splendid girls. I shall tell you, for it would not be unseemly in speaking to girls such as you to tell the truth. My name is Dos, for that is the one my dear mother gave me. Now I have come from Crete upon the broad back of the sea, although I did not want to. Men, pirates they were, they took me away by force. Later, they put their swift ship in at Thoricus. There, a crowd of women came down to the sea and prepared a meal for us by the stern cables of our ship. But I had no desire for the pleasure of food. In secret stealing away through the dark land, I fled my vile captors so they might not sell me and have enjoyment of my price. Thus, I wandered about and now have come here - although I don't know just where I am nor who these people are who live here. But may all the gods on Olympus give you good husbands and may they grant that you bear as many children as you wish. Pity me, girls,...
> [lacuna: and tell me (?)]
> ... dear children, to whose house I should go to find proper work, doing the sort of tasks old women do: to nurse a new-born child, holding him in my arms. I could also keep the house and make the lord's bed, the bed that lies deep within the well-built chambers, and I could teach the women their work.'

So the goddess spoke, and the unwedded virgin Callidice answered her, Callidice, the best-looking of the daughters of Celeus:

> 'Old Mother, poor mortals must endure what the gods dole out because they are much our betters. Ah, but let me explain it to you clearly and tell you the names of the men who are important, the ones honored in our town and who rule our people and guard the citadel, that sits like a crown upon our city - the ones who counsel us and keep our peace. There is Triptolemus, the wise, and Dioclus and Polyxenus, irreproachable Eumolpus and Dolichus and our own valorous father; and all of them have wives who keep their houses. And none of them on first seeing you would dishonor your person and send you away. Rather, they will welcome you because you are like some god. If you wish, stay here and we will go to our father's house to tell Metaneira, our mother Metaneira who wears her belt low over her hips we will tell her everything from start to finish. And we will see if she wants you to come to our house rather than go seek some other. She has borne a son late in her life and is nursing him in her well-built chamber, a

> child most prayed for by us all. If you nurse and raise him and he reaches young manhood, then all women when they see you will envy you - so many will be the gifts she will pay you for rearing him.'

She said that and the goddess shook her head in assent. The maidens then filled their shining vessels with water and carried them home rejoicing. Quickly they arrived at their father's great mansion and quickly they told their mother what they had seen and heard. And she bade them go quickly to call the old woman and offer her a handsome wage. As deer or young heifers frolick in the meadows, sating themselves with the new shoots of springtime, thus the maidens as they held the folds of their gossamer robes rushed along the grooves of the wagon trail, their hair tossing about their shoulders like crocus blossoms, saffron and gold. They found the glorious goddess near the road, just where they had left her. Then they led her to their father's house and she walked behind them with a heavy heart, draped from head to foot, and around the delicate feet of the goddess, her dark robe fluttered. Soon they arrived at the house of Celeus, whom god favors, and they went through the corridors until they reached their mother, lady Metaneira. She was sitting by a pillar and was holding her new offspring, her son, on her lap. The girls ran to their mother's side; then Demeter stepped to the threshold, her head grazing the roof beam - and the doorway was filled with her divine aura. Awe and reverence seized the mother and she grew pale from fear. She rose and begged the goddess to be seated on her own chair, but Demeter, the goddess who brings forth the seasons and gives us splendid gifts, did not choose to be seated on the glittering chair; rather, she stood in silence with her beautiful eyes cast down, until the scheming Iambe gave her a stool and threw a gleaming ram's fleece over it. Sitting there, she drew her veil across her face and for a long time sat grieving, speechless as she sat upon the stool. Nor did she say or do a thing; she just sat mirthless, with a taste for neither food nor drink, wasting away because of her desire for her daughter. Thus she remained until the scheming Iambe amused her with jokes and made the holy lady smile, then laugh, softening her heart - Iambe who in later times pleased her at her rites of Mystery. Metaneira offered her a cup filled with wine, as sweet as honey, but she refused it, telling her the red wine would be a sacrilege. She asked instead for barley and water to drink mixed with tender leaves of *glechon*. Metaneira made the potion and gave it to the goddess as she had asked; and great Deo received the potion as the precedent for the Mystery...
[lacuna of 22 to 26 lines]
... Metaneira, whose robe hung in thick folds about her hips, said to her:

> 'Greetings, woman, I do not think you are of low parentage, since modesty distinguishes your looks and grace, as if you were descended from a line of kings, who administer justice. But we poor miserable mortals must suffer what the gods dole out and it seems a yoke of misfortune encircles your neck. Now since you have come here, what's mine shall be yours also. Nurse this child of mine: the gods granted him to me late in life when I had lost all hope of bearing him, and I prayed for him often. If you nurse him and he reaches young manhood, then all women when they see you will envy you - so many will be the gifts I shall pay for raising him.'

Demeter, the goddess who wears a splendid crown, then answered her:

> 'Greetings to you, woman, may the gods bless you with all that is good. I shall gently rear your child as you have bidden me. Have no fear for his safety, for he'll suckle the milk from no wicked nurse nor risk incantations that possess a babe nor will he taste of witches' root; for I know the powerful great herbs that are gathered and the talisman plant that wards off possession.'

So saying, she lifted him in her immortal hands and held him to her fragrant breast; and his mother rested content. Thus Demeter nursed the handsome son of wise Celeus, the son whom Metaneira bore, Metaneira whose robe hung in thick folds about her hips. The child flourished and grew like a god, for he fed not on mother's milk, but upon ambrosia, the food of gods, with which Demeter anointed him - anointed as if born a god himself; and she inspired him with her breath sweetly as she rocked him in her lap and at night she would bury him in the powers of the fire upon the hearth. But his parents knew none of this, and to them he was like a miracle, a kind of prodigy, somehow divine. The goddess would have made him ageless and immortal had it not been for the folly of Metaneira, his own mother. One night, watching from the sweet-smelling chamber, she spied upon the goddess at her magic and deranged by what she saw shrieked and beat her thighs in terror for her child. Horror-stricken she let forth this torrent of words:

> 'That woman, a guest in my house - dear Demophoon - she is burying you in a great fire and she

> leaves it to me to mourn and bear the pain of grief.'

So she wailed in anguish and the goddess who is a goddess amongst goddesses heard her. Enraged with her folly, Demeter, whose crown is splendid, grabbed the child from the fire and threw him to the ground, the son Metaneira had borne, the one for whom she had lost all hope - and so furious was her heart that she said to Metaneira:

> 'All men are fools! They lack the sense to foresee their fate as it comes upon them, good or ill, whatever it be. You, because your head is witless, it is you who have caused this irreversible mistake. Let the oath of the gods be known, the oath that is sworn by the unassuaged deathless water of the River Styx: I would have made this son ageless for all of time and I would have granted him undying honor, but now he can never escape the demons that bring his death. Yet he has rested on my lap and slept in my arms, and for that he will always have undying honor: in remembrance of him, all in due course as the season returns, young Eleusinians will always join together in contest and battle again and again.'
>
> 'I am Demeter, the one supreme in honor, for I am the source of life and joy both for mortals and immortals. This is what you must do. Have all your people build me a temple with an altar before it, beside the fortress of the high city that looms above Callichoron Well. And I myself shall institute my rites so that you may perform them and so conciliate my wrath.'

As she said that, the goddess was transformed, as if a wind had blown off her old age and left but her glorious beauty; her robes exhaled sweet perfumes, her skin radiated the aura of the immortals, and her golden hair covered her shoulders. The palace was filled with a brilliance such as the brilliance lightning gives. Then she turned and walked out of the hall.

When she had gone, Metaneira stood trembling and for a long time remained speechless, nor did she remember to pick up her beloved child from the floor. But his sisters heard his pitiful cries and rushed from their beds, beds that were strewn with rich coverings. Then one of them picked up the child and laid him on her lap. One rekindled the fire, while another raised up her mother and hurried her out of the fragrant room upon her delicate feet. Next they bathed the trembling child, fondling him, hoping to calm him after what had just happened, but he could not be assuaged - no matter how well they nursed him, they could not compare with Demeter.

All night long they propitiated the glorious goddess as they trembled in fear and when dawn appeared they told the whole truth to powerful Celeus, as the goddess had commanded them, Demeter, whose crown is splendid. Then Celeus called his many subjects to an assembly and commanded them to build an opulent temple for Demeter, whose hair grew in rich plaits as only a goddess's does, and he told them to build an altar on the rising hill. And as soon as they heard his voice, they obeyed him and built the temple as he had bid them. And the temple grew under her help.

When they finished the temple and had stopped working, they went home, each to his own house. But golden-haired Demeter remained there sitting apart from all the blessed gods, wasting away with longing for her daughter, Persephone whose robe hung in thick folds about her hips. Then she made a deadly year for mankind, withering the soil that is so nourishing, and Earth would not send up seeds because Demeter, the goddess who wears a splendid crown, kept them hidden. In vain the oxen pulled the curved plowshare through the fields, and much white barley fell to the earth, where it was wasted. And now she would have destroyed the whole race of mortal men by famine and robbed the gods of their honors and sacrifices, the gods who have Olympus for their home, had not Zeus perceived this and pondered it in his heart.

First he sent Iris, who flies on wings of gold, to call upon Demeter, whose hair grew in rich plaits as only a goddess's does and whose face glows with beauty. That was his decision and Iris obeyed Zeus, the storm-black son of Cronus. Swiftly she cut through the sky and arrived at the city of Eleusis, where incense perfumes the air. She found Demeter in her temple wearing the dark robes of a mourner, and she spoke this flutter of words:

> 'Demeter, father Zeus calls you to come rejoin the undying race of the gods who will always be.
> Come now, don't let my message from Zeus go unheeded.'

That's what she said, imploring her, but Demeter's mind could not be changed. Then father Zeus sent out all the blessed gods and one by one they went to her and called upon her and gave her many splendid gifts and let her choose as much honor as she might want among the immortals. But no one could persuade her to change her mind since she was so angered, and she stubbornly ignored their pleas. She said she would never again set foot on fragrant Olympus or let the earth bear fruit unless she saw her beautiful daughter with her own eyes.

Finally Zeus heard this, Zeus the thunder god, and he sent Hermes, who carries a golden wand, into Erebus, Hermes whom they call the Argus-killer because he slew that hundred-eyed monster, and now Zeus sent him that he might exhort Hades with soft words to let him lead holy Persephone out of the sunless west into the light. Then her mother would see her with her own eyes and seeing her, change her temper.

So, leaving the seat of Olympus, Hermes obeyed and rushed through the hollows of the earth. He found the lord of the dead seated in his house on a couch with his awesome wife, but it was not her will that kept her seated there since all she could will was her mother. But her mother was far away, thinking over what the gods had done. Standing nearby, the mighty slayer of Argus addressed him:

> 'Lord of Death, you Hades whose hair is purple, father Zeus commanded me to lead glorious Persephone out of Erebus back to us gods so that her mother, when she sees her with her own eyes, will stop her wrath and her horrible anger against the immortals - because she is planning a great act of vengeance: she is going to destroy the feeble race of mortals who dwell on the earth; this will she do by keeping the seeds hidden underground and so will she cause the honors that are paid to the gods to perish. She has a furious wrath and won't mingle with the gods; instead she sits apart from us in her fragrant temple, which is scented with incense, and she holds as her domain now the rocky citadel of Eleusis.'

He said that and the lord of the dead, Aidoneus, smiled and raised his eyebrows nor did he disobey the command of Zeus the king. Hurrying, he gave these commands to Persephone, the queen of miracles:

> 'Go, Persephone, to your mother, the lady who wears deep purple robes, and have a kindly spirit in your breast and be not so despondent. I will not make so bad a husband for you amongst the immortals - after all, I am Zeus's own brother. When you are there in his realm, you will rule over all the plants that grow and all moving creatures. Yours will be the greatest honor amongst all immortals and anyone who fails to make sacrifices to you and does not perform your rites or forgets to offer you appropriate gifts will learn the consequences.'

He said that and Persephone rejoiced and quickly jumped up from her throne in glee. But he, himself, gave her in secret a sweet pomegranate seed to eat so that she might not remain forever with her mother, the awesome Demeter whose robe is a deep purple. Then Aidoneus, who rules over many, harnessed his immortal horses to a golden chariot. Persephone got into the chariot and beside her sat the mighty slayer of Argus, Hermes, who held the reins and a whip in his hands. And they sped through the hall with horses eager to fly. Quickly they made the long journey back and neither the sea nor the waters of the rivers could hinder the flight of such immortal horses, no, nor even the grassy valleys nor the mountain tops, but always onwards did they cut through the air over the very mountain tops like a ship through the deep ocean. And then Hermes stopped them where Demeter was waiting in front of her temple perfumed with incense; and when she saw her daughter, she ran to her as a maenad racing through a mountain wood runs.

[387-405 badly mutilated; restoration uncertain]

And Persephone, for her part, when she saw her mother's beautiful eyes, leapt from the chariot and fell on her knees, covering her mother with embraces. But while Demeter still was caressing her child and holding her in her arms, she thought with horror - a trap - and trembling with her fear, she stopped fondling her beloved daughter and spoke these words:

> 'My child, when you were below the earth, did you eat any food? Tell me the truth and don't hide anything from me, so that we both may know. Because if you didn't accept his hospitality, you can flee from the halls of that loathsome Hades and dwell with me and your father, the storm-black son of Cronus, where you will be honored by all the immortals. But if you did eat anything, you will have to make the journey back again to the depths of the earth and live with Hades for a third

> part of the seasons of the year and stay here with me and the other immortals for only two of the three. When the earth abounds with all the fragrant blossoms that come with Spring, then from the sunless west out of the dark night you'll rise and appear as a great miracle to the gods and mortal men.... [lacuna]... And with what trick did the god who receives all deceive you?'

Persephone, most beautiful, answered her:

> 'I will tell you everything just as it truly happened, Mother. When Hermes came to me, Hermes the helper and swift messenger of the gods - when he came, beseeched by my father Zeus, son of Cronus, and by all the other gods who live on Olympus when he came to lead me out of Erebus so that you could see me with your own eyes, he came so that you would cease your wrath with the immortals and calm your terrible anger. So he came and I jumped up for joy, but he - Hades - forced upon me a pomegranate seed, forced it upon me against my will so that I would eat it - and I did eat of that sweet fruit.'
>
> 'And I'll also tell how he seized me according to the plan of my father, the son of Cronus, and brought me into the hollows of the earth. I'll tell you all this, everything you have asked.'
>
> 'All of us were playing in a lush meadow, my friends and I - Leucippe and Phaino, Electra and Ianthe - and I was playing with Melite, Iache, Rhodeia and Callirhoe, Melobosis and Tyche, and also with Ocyrhoe, who is as beautiful as a flower herself. There were also Chryseis, Ianeira, Acaste and Admete, Rhodope, Pluto and Calypso, whom all men desire. And with us were Styx and Urania, lovely Galaxaura and Pallas, who spurs on battles, and Artemis, the archer. Thus we all played, all virgins and fullbloomed in youth: we gathered the blossoms of earth in our hands, flower gathering flower - bouquets of gentle crocus, iris and hyacinth, rose buds and lilies, gorgeous to see. And there was a narcissus - the wide earth had brought it forth, glorious as a crocus, a jewel - and in ecstasy I spied it and plucked it, but the earth gave way beneath and from her burst the great lord Hades, who receives many. In his golden chariot, he carried me beneath the earth and I struggled all unwilling, screaming shrill a lament.'
>
> 'Wretched though it makes me, I have told you the whole truth.'

Thus they were in harmony with each other and for the whole day they comforted one another and their embraces finally softened their grief, each receiving and giving joy. Then to them came Hecate, who wears a delicate veil and she also caressed the daughter of holy Demeter and from that time on, lady Hecate was the servant and companion of Persephone.

Zeus, the thunder god, sent a messenger to them, Rhea whose hair grew in rich plaits as only a goddess's does, and she was sent to lead back Demeter, whose robes are purple dark, to the race of the gods. Then Zeus promised to give her whatever honors she wanted from the immortal gods. And he consented to the plan that the girl spend a third part of each spiraling year in the dark where the sun goes down, but that two-thirds would be spent with her mother and the other immortals. That's what he said, and the goddess did not disobey Zeus's message. Swiftly she fled down from the peaks of Olympus and sped to the Rarian plain.

Formerly this plain was the richest of fields that give life, but at this time it gave no life at all, lying waste, barren and all leafless. And the white barley was hidden in the earth by Demeter's plan. But in a little while, as the springtime progressed, it would be waving long ears of grain like a mane in the wind and its fertile furrows would be filled with grain lying at harvest, while other ears would be bound in sheaves. It was in that field that she alighted first out of the uncharted sky. When the goddesses saw each other, they embraced and rejoiced in their hearts. Then Rhea, who wore a delicate veil, said:

[462-70: text damaged; reconstruction uncertain]

> 'Come, my child, Zeus the thunder god calls you to come rejoin the race of the gods and he promised whatever honors you might want from the other immortals. He agreed that your daughter spend a third part of each spiraling year in the dark where the sun goes down and the other two-thirds with you and the other immortals. That's what he said was to be and he nodded his head in assent. So come, child, and obey and persist not in fighting with the stormy son of

> Cronus, but once again give the earth's fruit to mankind.'

That's what she said. And she was not disobeyed, for as soon as she had finished speaking, Demeter made fruits spring up from the rich plowlands, and the whole wide world became heavy with leaves and flowers. Then she went forth to the kings who administer justice, Triptolemus and Diocles, who drives horses, and mighty Eumolpus and Celeus, the leader of his people. To them, she showed the performance of her rites and taught her Mysteries - holy rites that are awesome, that no one may transgress nor reveal nor express in words, for an overwhelming reverence for the gods stops his voice. Whoever among men who walk the earth has seen these Mysteries is blessed, but whoever is uninitiated and has not received his share of the rite, he will not have the same lot as the others, once he is dead and dwells in the mould where the sun goes down.

And when the goddess among goddesses had taught them everything, she went to Olympus to be in the company of the other gods. There the two goddesses live with Zeus, who delights in the thunderbolt, and they are holy and revered.

Whomever the goddesses love among men who walk the earth, he is blessed, for they soon send Plutus into his great house to live at his own hearth, Plutus who gives wealth to mortal men.

But come now, you goddesses who preside over the town of Eleusis, where incense perfumes the air - you two who also have domains on Paros, which the sea surrounds, and in mountainous Antron - you lady Deo who brings in the seasons and gives splendid gifts, you and your beautiful daughter Persephone, come now grant me an easy life for my song. And still again may I pray to sing you a song.

Foreword by Richard Evans Schultes

On April 15, 1969 Mr. R. Gordon Wasson, Honorary Research Fellow in our Botanical Museum, brought out his *SOMA Divine Mushroom of Immortality*. In it he proposed a novel identification for Soma, the long enigmatic god-plant of the ancient Aryans, as *Amanita muscaria*, the brilliant red mushroom with white spots that is common in the birch and pine forests of Eurasia.

In June 1971 the Bulletin of the School of Oriental and African Studies (the '*BSOAS*') of the University of London published a 31-page article by John Brough, Professor of Sanskrit in the University of Cambridge, challenging the thesis developed in Mr. Wasson's book. On Sunday August 8, 1971 Mr. Wasson was host to Professor and Mrs. Brough in his home in Connecticut and on that occasion Professor Brough gave him an autographed copy of his paper, the first that Mr. Wasson had seen of it. On January 12, 1972 Mr. Wasson sent off his rejoinder to the *BSOAS*. On February 15 the Editorial Board declined to publish it, adhering 'to its general policy of not publishing rejoinders to reviews'. Thereupon Mr. Wasson on March 14 asked for the privilege of reprinting privately the Brough paper to accompany his reply elsewhere. So far as we know, the Board never took action on Mr. Wasson's request of March 14.

Following my return from a field trip in the upper Amazon and after familiarizing myself with all the facts, I decided that our Botanical Museum should publish Mr. Wasson's answer, and he fell in with my suggestion. On May 25 I addressed a letter to Professor Edward Ullendorff, M. A., D. Phil., F. B. A., Chairman of the Editorial Board of *BSOAS*, apprising him of our intention and soliciting permission to reproduce Professor Brough's paper together with the Wasson rejoinder. I expected this to be granted as a matter of course. On June 20 the Board finally declined to grant us the requested permission.

Together with Mr. Wasson I deplore the decision of the *BSOAS* Board not to allow us to reprint the Brough paper. In matters of moment editors should not feel hamstrung by their own house rules. Professor Brough may feel that it is unfair to him for Mr. Wasson's reply to go out unaccompanied by his text. But the Wasson rejoinder has now been so re-phrased as to stand adequately on its own feet. The journal in which Professor Brough's evaluation appeared is of limited accessibility to specialists in the diverse fields that the Soma problem will interest. While it would have been helpful to our readers, and only fair to Professor Brough, to have the Brough review before them, in the light of the decision of the *BSOAS* Editors, there is nothing that we can do about it.

On a larger stage, we deplore the decision of the Editors of BSOAS because we believe that a learned journal has a duty to encourage, rather than impede, the interchange of scholarly views. The mystery of the Soma plant reaches beyond questions of Vedic exegesis. The collection of hymns known as the *ṚgVeda* is a seminal document in Eurasian man's early history, and, as the Vedist Louis Renou wrote, the whole of the *ṚgVeda* with its problems is present *in nuce* in the themes that Soma presents to us. If the Vedists make no effort to identify the plant, others must undertake the task. As is common knowledge, over the past two decades notable achievements have been made by the Swiss team of Conrad Eugster and Peter G. Waser in the analysis of *Amanita muscaria* and the study of the properties of its constituents. Apart from many other matters, Mr. Wasson presents what seems to be telling evidence, especially to scientists, that the Brahmans of Vedic times were privy to the secret of those properties, unique so far as we now know in the plant world. He takes advantage of this paper to reformulate succinctly, in the light of all the discussion provoked by his book, the case for his identification of Soma and carries the argument into new ground.

The Soma question does not interest chemists and pharmacologists alone. It impinges on botany and especially on that field of botany which concerns itself with the psychotropic plants. It bears on anthropology and archæology, on religion and the early cultural history of Eurasia. Paraphrasing Georges Clemenceau on war and the generals, I would say that Soma and the *ṚgVeda* are too important to be left to the Vedists.

Introduction

When the *ṚgVeda* was first revealed to the West after the middle of the last century, it aroused excitement and lively expectations in cultivated circles. But in recent decades that nascent enthusiasm has been receding, largely no doubt because of difficulties inherent in the text but also because many Vedic scholars have been content to live in isolation in what looks to the outsider like an hermetic coterie. This attitude is exemplified at every level, conscious and unconscious, in Professor Brough' s painstaking dissection of my *SOMA Divine Mushroom of Immortality*.

The *ṚgVeda* is unique in various ways in its antiquity, in its textual purity, and in the strong though narrow beam of light that it throws on the religious and spiritual life of one element in our Eurasian ancestry just as it was emerging from pre-history. There was always the enigma of Soma. With the strides made recently in exploring for psychotropic plants, Soma, permeating the *ṚgVeda*, cries for identification at last. But following the example of their Hindu predecessors, Western Vedists have chosen to ignore this question and some even seem to resent a proffered solution, saying that the problem is insoluble without having made an effort to solve it.

With two of John Brough's pronouncements in his review article[1] on my *SOMA* I agree. 'The importance of the Soma-plant in Vedic religion has never been underestimated. ... the *ṚgVeda* is, so to speak, permeated by Soma'.[2] Here he is right. Soma is indeed the key to the 1028 hymns of the *ṚgVeda*, and that key was long since mislaid. Brough goes on to call my views 'revolutionary',[3] and again he is right. I was waiting for someone of stature to say this. That he devotes 31 pages to me in the *BSOAS* is in itself a recognition of the importance of the issue I raise. As this issue has wide bearings, reaching in diverse directions far beyond Vedic circles, he must expect me to discuss his views on their merits, according to my lights, not letting personal attachments affect my findings. This was his way in writing his review. I welcome his paper, supplying me as it does with a number of texts that allow me to clarify, amplify, and drive home my thesis.

Near the beginning of his paper Brough has this to say about the Siberian materials that I offer my readers in *SOMA*:

> ... as a matter of simple logic, such parallels have no probative value. They cannot even be adduced as confirmatory arguments for the theory that the Soma-plant was *A. muscaria*. Until this theory is proved for the *ṚgVeda*, and proved beyond any possible doubt, the non-Indo-Iranian materials remain, in the strictest sense, irrelevant. Even if the proposed identification for Soma seems probable, but is not proved on the basis of internal evidence, extraneous facts are not additional evidence. [JB 332-333]

Any such proposition is, I submit, untenable. How ambivalent is Brough's guidance line! Even though a 'proposed identification for Soma seems probable' what a big concession! - 'if not proved on the basis of internal evidence', it carries no weight with him as a Vedist. By this rule Brough achieves two ends: the exclusion by fiat of the testimony of my photographs, and unless I have misunderstood him the exclusion of non-Vedists from the field, for only accomplished Vedic scholars can pass on the internal Vedic evidence. By contrast I hold that the Soma problem has the widest cultural ramifications and it can only be met by drawing on the resources of diverse disciplines. The sterility of the traditional manner of handling the Soma enigma is manifest.

Brough goes further: the Vedic scholar may not advance an identification of Soma on what lawyers would call the weight of the internal evidence, nor yet on evidence proving his case beyond a reasonable doubt, as in a criminal trial. The proof must be 'beyond any possible doubt'. To exact unanimous agreement among Vedic scholars on a novel interpretation of the Vedic evidence is chimerical: there will always be dissenting voices, as Vedic scholars including Brough well know. What Brough is saying is that the identification of Soma is impossible, and one re-reads Brough's words at the end of his opening paragraph with fresh understanding as the full reach of its chilling sense dawns upon us; '... and the opinion is widely held that the problem is insoluble'. Can it be that many Vedists today hold to such a despairing view? Is the anonymity of Soma a built-in element in Vedic studies and are Brough and some other Vedic scholars content, perhaps determined, to have it so?

But no Berlin Wall sets off the *ṚgVeda* hymns in an encapsulated enclave. They are just one area of many - though a particularly fascinating and important one - in the republic of humane letters. Where would Biblical criticism be if Biblical scholars had not taken soundings in all the adjacent cultures and not least the non-Semitic ones? Where would Homeric studies be if a Schliemann had not gone beyond the text to look for Troy? Nor have the scholars in these fields hesitated to enlist the help of scientists in devising techniques to date and assess their archæological finds. Has Brough read *Science and Civilisation in China* by his colleague of Gonville and Caius College, or, if he has, has he failed to catch its message? Not all Vedic scholars share Brough's attitude, but he does not stand alone. F. B. J. Kuiper of the Kern Institute in Leiden has said that 'the search for the "original Soma" might lead us far beyond the field of Indo-Iranian studies proper',[4] as though such excursions were dangerous temptations to be avoided. These two statements, Brough's and Kuiper's, reveal the absurd isolation in which some Vedic scholars live by choice. I should have expected Vedists to be foraging in all the highways and byways of science and the humanities for clues to the all-important enigma of the mysterious Soma. I should have expected all (not just a few) of them to welcome suggestions from those specializing in other disciplines such as botany, where the explorations for the hallucinogens have lately thrown wide the door to new interpretations in cultural history. I should have expected the Vedists not only to be abreast of the thrilling developments in the botanical exploration for the psychotropic plants of the world but to be pioneers in it, contributing suggestions from the *ṚgVeda* for identifying Soma. But many are not informed, not interested, and they resist suggestions. The fruits of interdisciplinary exchanges are to be rejected out of hand, in advance.

The Vedists with notable exceptions seem to be, as it were, the heirs to the Brahman caste, not touching ordinary mortals and not to be touched by them. True, in the rest of his paper Brough comes down into the market-place to rub elbows with the commonalty, and his friends may point out that he fails fortunately to live up to the rules laid down in his opening paragraphs. But this initial declaration of his, all the more meaningful for being a forthright admission, gives us the cast of his mind, discloses his attitude toward traspassers in the Vedic preserve.

I seize this opportunity to call public attention to an extraordinary act of scholarly elegance on Professor Kuiper's part. He sent me his review when it was written, months before its publication, and on my suggestion opened the columns of his *Journal* to my response, allowing me to appear in the same issue with his review and following immediately after it. Not only this: his review was printed in 8-pt type on a 9-pt slug whereas my reply was in 9-pt type on a 10-pt slug, making my paper more readable than his! In this case the characterization 'a scholar and a gentleman' is no mere *cliché*.

II

Chemistry and Pharmacology

I will start with the chemistry and pharmacology of the fly-agaric, *Amanita muscaria*, the plant that I am confident (more so than when my book came out, now that I begin to see what the opposition amounts to) was the Soma of the Aryans.

In our generation the pioneers and leaders in this research have always been Conrad H. Eugster, Professor of Chemistry in the University of Zurich, and his colleague Peter G. Waser, Professor of Pharmacology, with whose papers Brough was unacquainted.[1]

Eugster's isolation of two new chemical entities in the fly-agaric, now called 'ibotenic acid' and 'muscimol', has been the epoch-making discovery to date in fly-agaric research. At first unveiled only in patent applications, they were revealed in a doctoral dissertation in Zurich in 1961. Both entities are psychotomimetics, or, in popular language, hallucinogens.

And here we come upon startling facts. Ibotenic acid is present in the fresh fly-agaric in widely varying amounts, ranging from 0.03% to 0.1%. When the fly-agaric dries, the ibotenic acid steadily disintegrates and disappears. It is replaced by muscimol, *which is at least five times more powerful*. Thus we have the unique situation where a psychotomimetic agent converts itself through simple drying into another active agent that is more potent by far and more stable. In *SOMA* I give *in extenso* (and in summary on pp. 153 ff) the almost unanimous testimony, extending over two centuries and throughout almost the whole of the northern tier of tribes from the valley of the Ob to the Chukotka, that the fly-agaric must *not* be eaten fresh: it should be dried, preferably sun-dried. The empirical knowledge of the Siberian natives is now confirmed by Eugster. Furthermore Eugster says that Swiss mushrooms gathered in mid-summer carry more ibotenic acid than in autumn. This echoes the testimony of von Langsdorf[2] about the practice of the Kamchadal of using mushrooms gathered in July and August. Thus these discoveries of Eugster's at the laboratory bench only confirm what the unlettered Siberian tribesmen have known empirically from time immemorial. My *SOMA* was in Eugster's library, but as he fails to mention the evidence from Siberia, I can only conclude that this element in it failed to catch his attention.

The testimony is abundant though not unanimous that the Siberian tribesmen, after having dried their fly-agarics, on ingesting them washed them down with water, or with the juice of berries (bilberries *Vaccinium uliginosum* or willow herb *Epilobium angustifolium* - or perhaps other berries), or thoroughly worked them over in human saliva. Alcohol is never mentioned and Krasheninnikov in the mid-18th century says expressly that the mushrooms were soaked in the 'must' or 'wort' (Russian: *suslo*) of *Epilobium angustifolium*.[3] The parallel with the Vedic usage is remarkable. The dried mushrooms (in which the ibotenic add has been replaced by muscimol) are re-watered[4] in the elaborate Soma sacrifice, and later, after filtering, the *pávam&amacr;na* is mixed with milk or curds or ghee or barley water, or occasionally with honey (*mádhu*). Nothing authorizes us to say the *mádhu* was mead.[5]

Now listen to Brough:

> ... it would be strange that the elaborate Vedic process of pounding out and filtering the juice should have been necessary. Why should the plant not have been simply eaten? There is no particular sanctity in liquid as such. [JB 338]

Not sanctity but chemistry! The plant *must* be first dried, then re-inflated, and finally the juice expelled.

Brough goes on to say there is no mention in my exhibits of the 'pounding' of the mushrooms to extract the juice. No, there is no mention, nor of a Brahman caste singing hymns in the Vedic language.

The Vedic hymns marked a high point in the religious life of the Aryan people, in which the rapturous experience produced by Soma led the Brahmans to clothe the celebration of the sacrament in an amazing ritual, perhaps without parallel in history. Let us now travel down the corridors of time three thousand years, and through the corridors of space for thousands of miles, and we find some dozen tribes almost pushed into the Arctic Ocean, in cultural disarray, minuscule in numbers, disappearing before our very eyes, but still possessing (I submit) the same mushroom that the Aryans possessed, insisting that the mushroom was of an order superior to the alcohol of the West,[6] drying their mushrooms as the Aryans had dried theirs, only to steep them again in fluid in which water plays the operative role, consuming them, and then knowing rapture.[7]

Brough says he 'has no specialist qualifications in chemistry and pharmacology' [JB 360] and proceeds at once to supply documentary support for his lack of qualifications in a number of surprising statements in the chemical and pharmacological fields, *e.g.*,

> ... it is most probable that the muscarine is the chief nauseating agent in *A. muscaria*. [JB 360]

Since Eugster and Waser brought out their landmark paper in 1954 no informed person has entertained this notion. The drug muscarine is present in the fly-agaric in such small amounts that quantities far beyond human capacity would have to be ingested to provoke any kind of muscarine reaction. All that Brough says about the chemistry and pharmacology of *A. muscaria* is out of date.

A little later we come on this:

> ... much work remains to be done in botany, chemistry, and pharmacology before it will be sensible to make a further attack on the problem of the botanical identity of the Soma plant. [JB 361]

The readers of the *BSOAS* rightly look to the papers published therein for authoritative pronouncements in the fields under discussion and they may overlook Brough's warning that he is here speaking without credentials or they may skip over his disavowal of 'specialist qualifications' as only a standard *cliché* of false modesty. But the fact is that Brough shows no knowledge of the immense amount of work done and progress achieved in recent decades in psychoactive plant substances, and the fly-agaric is in the vanguard of these advances. At the last moment, when I caught wind of what was afoot, I sent him an elementary paper[8] that might have rescued him, but it was too late. In an Addendum at the end of his paper [JB 362] he graciously acknowledged receipt of the paper but then goes on to minimize the importance of his lack of 'specialist qualifications' by saying that the 'chief point of [his] argument still stands', *i.e.*, the 'nausea, vomiting, and coma caused by the fly-agaric', as though these effects were absolutes, not arguable, not subject to definition, to qualification, to circumstance. But let us reflect a moment. Wine as one of the Elements in the Mass is analogous. From earliest times (indeed since Noah's days!) wine has been known to cause nausea, vomiting, and coma; yet its sacramental rôle stands unchallenged.

Brough speaks of the work that remains to be done in botany, chemistry, and pharmacology before we can tackle the botanical identification of the Soma-plant. But if Vedists persist in remaining ignorant of the work that has been done and is being done in these other disciplines, his formula for progress leads to a dead-end. For Brough would confine work on the *ṚgVeda* to Vedists, and since most Vedists, and not least the good ones, are unlikely to have time to master botany or chemistry or pharmacology, the outlook is bleak.

But of course Brough is mistaken in claiming for Vedists pre-emptive rights in the *ṚgVeda*. He is wrong in his *noli-me-tangere* stand, which is simply a *déformation professionelle*.

1. ↑ For the bibliography of their papers, see Appendix I. They supply the names of two other teams, one Japanese and the other English, that have concerned themselves in the '60's with the fly-agaric.
2. ↑ See below Appendix II; also my *SOMA*, p. 247.
3. ↑ By definition 'must' or 'wort' is a non-alcoholic juice but a juice destined for fermentation. We all know that in popular usage 'must' is sometimes applied to a beverage that has begun to ferment. Krasheninnikov was a scrupulous reporter, and if

alcohol had been involved I think he would certainly have told us so. Besides all of the rest of the dozen witnesses are unambiguous: water (sometimes sweetened with berry juice), not alcohol, was the vehicle that the natives relied on. ... Only Brough can explain why he misrepresents the Siberian sources saying that in Siberia 'the mushroom is apparently always consumed whole' (JB 336), and repeating this error on JB 338, though this time qualifying it somewhat.

4. ↑ There are numerous verses in the *ṚgVeda* alluding to the reflation of the dried Soma: *e.g.*, IX 30.5, 62.5, 79.4. W. Caland and V. Henry in their classic *L'Agniṣṭoma* (Paris, 1906-1907) say that the Soma plants were mingled with water on the second day of the prolonged ritual (§ 47) that they were describing, and the pressing and filtering took place only three days later (§ 127), on the fifth day. In the ritual that they give us the original Soma was no longer being used, but the steeping in water that they report must have come down from earlier times, since there could be no point in inventing at a later date such a conspicuous feature of the liturgy, a feature that would be otiose with a substituted plant. The Soma sacrifice was ordinarily much simpler and briefer than the lengthy *Agniṣṭoma*, which is useful in giving us as it were a slowmotion picture of the sequence of events.

   The author of a review of *SOMA* that appeared in *The Times Literary Supplement* (22-V-69) denied that there was 're-hydration' (as he called the reflation) of Soma in the Vedic ritual. He had simply overlooked the numerous verses in the *ṚgVeda* referring to it, as well as the evidence in *L'Agniṣṭoma*. The reviewer was also certain, if Soma had been a mushroom, that the priests, when they gave up Soma, would have chosen another mushroom as a substitute. But no one is privy to the motives of the Brahmans of B. C. 1000. It seems to me that if they found it advisable to abandon Soma, the circumstances were probably such that they would wish to obliterate its very memory. The Brahmans were skilled in memory disciplines and had they desired to perpetuate the memory of their sacred plant, nothing could have been easier. The review ended with a frivolous (though in the critic's opinion serious) suggestion that the *chanterelle* (*Cantharellus cibarius*) was the original Soma. Eminent scholars, sheltered behind the anonymity of the TLS reviews, sometimes as here are careless and irresponsible in their handling of serious books.

5. ↑ Henry Wassén, Director of the Gothenburg Ethnographical Museum, a shrewd, widely read, widely traveled man, in conversing with me has always urged upon me, first, the key significance among the Paleosiberian shamans of the fluid that they took with the fly-agaric, and secondly, the psychological importance of the unanimity with which they tell, on returning from an ecstatic trance, of the far journeys they have been on. We now see the meaning of the fluid that they imbibe. I next draw attention to the following footnote in *L'Agniṣṭoma* (p. 450; preceding ftnt.), speaking of the Vedic hymns:

   > ... le sacrifice [fut] souvent métaphoriquement assimilé à une marche, un voyage, une expédition, et comportant d'ailleurs réellement un grand nombre d'évolutions processionelles.

   In short, in that distant Aryan land Caland and Henry as early as 1906 gave us, in discussing Soma, a description of what today, in popular parlance, is called a 'trip.' The analogy with the Siberian tribesmen as well as with today's use of hallucinogens is manifest.

6. ↑ *SOMA* 250: Von Langsdorf says, 'The Koryaks greatly prefer fly-agarics to the Russians' vodka and maintain that after eating fly-agarics a man never suffers from headaches or other ill-effects.' 267-268: Jochelson says, 'Like all other primitive tribes, the Koryak are passionate consumers of brandy, and dealers often obtain an arctic or red fox in exchange for one wine glassful of brandy. To my question as to which they preferred, brandy or fly-agaric, many Koryak answered, "Fly-agaric". Intoxication from the latter is considered more pleasurable, and the reaction is less painful, than that following brandy.'

The Persona of Soma: In the Beginning Was the Word

The juice of the Soma-plant caused divine inebriation, *mada* or *maδa* in Indo-Iranian terms.[1] The 'reverential awe' (Brough's words) that Soma inspired permeates the *ṚgVeda*. This reverence, this awe, prompts Brough to see an analogy with the Greek **ἐνθουσιασμός**, 'God-possessed', and rightly so. 'All the words concerning poetic inspiration', says Brough, 'appear in connexion with Soma', and he lists six such words, *dh&imacr;*, *dh&imacr;ti*, *mati*, *vip-*, *gir-*, *man&imacr;ṣ&amacr;*. Another term *kavi*, 'poet', is frequently applied to Soma, and *kā̆vya*, translated by Renou as *pouvoir-poétique*, 'poetic potency', is preponderantly applied to Soma and to Agni, two gods in the *ṚgVeda* who are closely associated together. A *kā̆vya* is an inspired utterance and also a magically potent spell, as Brough points out. He quotes Renou as equating *vā̆c*, 'the Word', in French 'la Parole', with the 'Logos' of Greek. All this is splendid. I would have added some comment on *amṛta*, a powerful synonym for Soma, used time and again, a word cognate with Greek 'ambrosia', the food of the immortals.

These Vedic words tell us what is essential about the effect of Soma on the Brahmans who were the custodians of its secrets. My reservation - and a grave one - is that Brough seems to find these words foreign to him. He is not at home with them. He cites Vedic verses and words. He quotes Renou. He thinks he finds a Greek word that is applicable:

> It is difficult to give an adequate equivalent [of *mada*], but the tenor of the hymns indicates something like 'possession by the divinity' in some way comparable to Greek ὁ ἐνθουσιασμός. [JB 339]

Why does Brough find it 'difficult' to render *mada*? Divine inebriation, divine possession - these are common coin of the realm where mystics and their commentators dwell. There has been no dearth of them from India to the Atlantic, from Vedic times down to today, in all the religions that we know anything about. I find it odd that a Professor of Sanskrit in Cambridge should not be at home in the idiom of the mystics. I do not of course insist that he be a mystic, but that with sympathetic understanding he should be attuned to them, listen to them, watch their performances, know their ways.

What is but a suspicion on the reader's part at this point is proved beyond a doubt a page later. Brough finds only one hymn[2] - and that a doubtful one - that may have been inspired by an 'hallucinogen', - only one out of 1028. After we have been told that Soma, permeating the *ṚgVeda* (as Brough himself says), the potent engine behind the hymns, leads to *mada* (divine possession), generates 'reverential awe', vibrates with the Word (*vā̆c*), makes for *kā̆vya* (poetic potency), when we are expecting Brough to lead us through the hymns and trace in them the all-pervading influence of these moving superlatives, when we are to be shown, in short, whither Soma took the poets, we are reduced to one dubious hymn, X 119. And why did Brough choose this one hymn? Is it only because each of its verses ends with a refrain, 'Have I not drunk the Soma juice?' An astonishing way to judge poetic inspiration! Let us suppose the poet had ended the verses of this hymn with a different refrain: Brough would not have cited it, but would it have been any less 'inspired'? Or let us suppose the poet of IX 113 had replaced his refrain with one mentioning Soma-juice: would this have made a difference? The poets were singing their hymns to each other, for those who knew the Way (*ṛtá*), not preparing road-maps for strangers thousands of years later and thousands of miles away.

Brough discovers a dichotomy between the 'inspired' hymns and the 'far more' that are liturgical. Why this dichotomy? Liturgy is the supreme communal expression of religious feeling. Liturgy is an enactment of a myth or a sacrament, and every word, every gesture, every posture, also the processions, solemnly performed by people duly appointed for the purpose, can be as inspired as Brough's 'inspired' hymns. When he thinks of the liturgical hymns, is he mistaking the rubrics, the 'stage directions', for the divine performance? In any case it is clear that Brough fails to feel the throb, the glow, the tingling sensation that the hymns conveyed to the priests who composed them, giving voice to the divine afflatus that moved the poets. Granted, religion has moved thousands of years and thousands of miles from the Vedic age, and to seize the poets' thoughts and feelings calls for highly developed empathy on our part. When the priests sang the opening verses of IX 74, with one numinous phrase after another, those in attendance must have felt the tug at the heart, their rising gooseflesh (as A:'E. Housman[3] put it on a celebrated occasion in Cambridge), their tear ducts perhaps working. This was what was meant by *kăvya*, and only at a lower level, among those who were incapable of reaching the heights of which I speak, did *kăvya* convey the mundane sense of Brough's 'magically potent spell' or incantation.

After dwelling at some length on the 'reverential awe' generated by Soma, after discussing the Vedic words that eloquently describe its effects, after thus supplying us with the peculiarity, the very signature, of an hallucinogen when consumed by one ready to receive it, the reader is startled by Brough's question:

> Yet, if we exclude this hymn [10.119], what indisputable evidence is there in the *ṚgVeda* that *soma* was hallucinogenic? [JB 341]

What additional evidence do we need? It is possible of course that Brough does not know an hallucinogen when he describes one. With an hallucinogen the 'reverential awe' of which Brough speaks imbues all the hallucinations of the five senses and together with them places one, for the nonce, among the Immortals. The 'reverential awe' holds one spellbound, entranced, for the time being, and nothing else matters. 'Reverential awe' is the hallmark of the hallucinogen.

In *SOMA* I suggested that the fly-agaric with its sturdy stanchion and resplendent capital happily coincided with the metaphor, 'mainstay of the sky' or 'pillar of the world', by which Soma is designated time and again in the *ṚgVeda*. Brough says on this:

> I find the idea almost comic that the Vedic poets should have seen in this little mushroom a model of the sky supported by a mighty pillar. [JB 357, lines 9 and 10]

Brough is admitting (his admission being spontaneous and therefore the more significant) how little he knows of the poetic idiom of the enraptured mystic, who often tries to convey the ineffable by hyperbole and paradox. 'And a sigh is the sword of an angel king,' wrote Blake. If Brough came across this line for the first time without knowing the author, would he not find the metaphor of a sword for a sigh almost comic? The same insensitivity to a powerful metaphor marks Brough's treatment of the knot-studded cudgel of Indra,[4] which also seems to have given Brough a merry time. We are postulating that the fly-agaric is the adored Soma. We are postulating that the Brahman poets knew divine inebriation from imbibing Soma, that they were gifted with *kăvya*, 'poetic potency', that they spoke the *văc*, the Word. We are postulating a Soma glowing with holiness. No appropriate figure of speech is too exalted, too extreme, for the Soma-plant.

I do not of course hold the view that the fly-agaric itself was the *fons et origo* of the metaphors 'Mainstay of the Sky', the 'Single Eye', the 'Head' of Soma, etc. The Vedic conception of the universe - the vault of heaven, *s&umacr;rya*, and all the rest - found a surprising number of parallels in the shape and colouring of the superb fly-agaric and the poets seized on them for their tropes. Their cosmological ideas and the plant reinforced each other most beautifully. But some of the figures, such as the 'First Filter', the 'knot-studded cudgel' of Indra, and the 'Third Filter' could only have originated in the fly-agaric.

The words *mada*, *kavi* and *kăvya*, *văc*, and the others listed by Brough - all emanations as it were of Soma - are the body and soul of the *ṚgVeda*. After citing them timidly, gingerly, Brough drops them for good. He embarks on the building of an utterly different, incompatible *persona* for this god, one with whom he seems at home. Brough thinks Soma is a stimulant; yes, a vulgar stimulant like alcohol, like the rum ration that has sometimes been given in the West to sailors and soldiers before entering a battle. Brough is sure about this Soma.

> On a more mundane plane, the *soma*-drink was a powerful stimulant for those about to go into battle. [JB 340)

Who drank Soma in Vedic times? The priests - or some of them - certainly, and perhaps the wealthy patrons of the cult also. But who tells us that the ordinary warriors did so? Brough speaks of 'the secular use of *soma* in battle'[5] as of a fact and he 'conjectures' that this use came first in time! I wish he had given us supporting evidence.

In the Vedic hymns Indra, the warrior god, as well as other deities, went into the fray against their mythological enemies with bellies full of Soma. But this is mythology, equipping the gods with the divine afflatus. The Brahmans conceived of their tribal gods fighting the enemy with full equipment, with *mada* and *văc* doing their part.

Brough quotes[6] in favor of his warrior interpretation of Soma *ṚgVeda* IX 30.3 where the poet says, 'Bring us warrior-might [exaltation of spirit as well as bodily strength] fit to subdue warriors'; and IX 85.2 where he says, 'O Pavam&amacr;na, stimulate us in the battle... strike down our enemies.' But these two verses sound like the hymns that were sung in churches all over the world without any 'stimulant' during the last wars. Soma and Indra are mighty tribal gods, they are 'our side', and they are urged on together to enter the fray and do valiantly. The Brahmans were singing hymns pleading with their gods, Indra, Soma, and the rest, expressing ardent hopes, praying for victory with the gods' aid. The men may have fought better after they had heard such a stirring religious service.

Brough reverts to the 'stimulating' effect of Soma time and again.

> There are ample grounds for believing that *soma* was a powerful stimulant. [JB 341]

What 'ample grounds'? He gives us no grounds at all.

> Here, it would seem, is a plant [*i.e.*, the fly-agaric] whose effects are totally unsuitable to stimulate Indra and human warriors for battle. [JB 360]

Yes indeed. At this point Brough is right. Soma stimulated the *kavi* to song, not warriors to battle.

> Ephedrine is a powerful stimulant, and would thus be a more plausible preparation for warriors about to go into battle. [JB 361]

But divine inebriation is what moved the *kavi* who imbibed Soma. *Mada* and *văc* are its sweet fruits, not lust to do battle.

Brough does not reconcile his two personalities of Soma. Would a leader commanding troops about to enter battle choose that particular moment to have his men awe-struck with holy rapture? But until Brough documents his construction of Soma as a 'stimulant' like our spirits, it is idle to speculate on the possibilities, enticing though this exercise promises to be.

Brough finds stupor incompatible with the Vedic religion.[7] How does a man in rapture look? There are many stupors and one kind is a man in rapture. Those Europeans who observed the tribesmen in Siberia did not know what they were seeing. They contented themselves with saying 'stupor' and they were right, but they did not look far enough. Everything that Brough holds against my theory on p. 360 is not only compatible with the fly-agaric as Soma but confirms it. He objects to the emetic properties of Soma, but in the East the attitude toward vomiting is far different from our modern Western attitude. We think vomiting a sign of illness or at least an imbalance in the organism, and in company vomiting is beyond the pale. Part of the yoga discipline is to extend the range of the voluntary nervous system to include vomiting and to vomit regularly. I do not assert that any such régime ruled 3,000 years ago in the Indus Valley, but I am fairly confident the Brahmans of the *ṚgVeda* did not share the modern Western conventional horror of vomiting, which I believe is limited to our own age and culture. Certainly once you are in a state of ecstasy, vomiting does not matter, as those who have experienced rapture well know.

Brough cites convulsions as caused by the fly-agaric. This must be based on von Langsdorf's testimony, pp. 248, 250-1 of *SOMA*. But von Langsdorf quotes informants as saying that convulsions are caused by *excessive* use of fly-agaric. Brough omits the word 'excessive'. He has reversed the tenor of his source. Furthermore von Langsdorf adds that cases of convulsions leading to death were 'extremely rare' and moreover, on inquiry, 'no one could recall any specific example'. (His informants were doubtless Russians exchanging hearsay in the Russian colony concerning the surrounding helots - the Kamchadal, Koryak, *etc.*) Brough does not quote von Langsdorf's careful *caveat* that covers this part of his text:

> Although I made great efforts to find out something about the harmful or possibly deadly effects of the fly-agaric, I could obtain no satisfactory information on the subject. The Koryaks greatly prefer fly-agarics to the Russians' vodka and maintain that after eating fly-agarics a man never suffers from headaches or other ill effects.

Brough seems to know little of the varieties of religious experience. The Vedic religion was not a sedate, decorous, conventional service attended by well dressed well behaved families such as we have on Sundays in the churches and cathedrals of England and the United States.[8]

Brough asks me in a challenging tone why I feel certain *mádhu* in the *ṚgVeda* never meant 'mead' but always 'honey'. I am quite sure that I am right and here are my reasons. Soma in the *ṚgVeda* is exalted above all earthly things. Soma is of the earth but it is also divine. It possesses the power to confer the 'reverential awe' of divine inebriation, the *pouvoir-poétique* as Renou phrased this gift that surpassed all other gifts. Soma was the Word made juice. Only metaphors of superlative enhancement were worthy of it. Repeatedly the term *mádhu* is so used. In the Vedic age honey was unique, a product of nature having the colour of amber and a heavenly taste, virtually the only source of sweetness that the Indo-Iranians knew. In this guise, *mádhu* was worthy of Soma. Who would downgrade Soma by calling it 'mead'? Mead is a fermented drink in a class with beer. If *mádhu* had meant 'mead', why was not *súr&amacr;* an equally common trope for Soma?

We in the West, by long tradition, are obsessed with alcohol as the sole inebriant. A divine inebriant is utterly different in kind from an alcoholic beverage. Would a believing Christian liken the Elements in the Holy Eucharist to the beer being dispensed in a local pub? *A fortiori* would the Brahman, possessing an herb whose miraculous potency did not need to be taken on faith, call this herb by the equivalent of beer? If the Aryan culture knew mead, I think the Aryans must have called it by another name and in I 117.6 the poet obviously meant 'a hundred jars of honey', the highly prized honey, not mead. Had the Brahmans commonly used the same word for both, honey and mead, the confusion of senses would have precluded *mádhu* as a trope for Soma. At the expense of repetition I repeat that a fermented beverage must not be confused with a divine inebriant. This is the first and great commandment for the Western student of Soma to master.

1. ↑ Brough's discussion here is JB 339-340. In the Trentino dialect of Italian the fly-agaric is *ovolo matto*, 'mad mushroom'. Some philologists have thought that this adj. *matto*, apparently a *hapax* or rare in Latin, now common in Italian, was cognate with the Indo-Iranian *mada*, *maδa*.
2. ↑ I refrained in *SOMA* from citing X 119 because of its late date, not feeling certain that Soma was still being consumed by the Brahmans when the last batch of hymns was admitted to the canon.
3. ↑ *The Name and Nature of Poetry*, Leslie Stephen Lecture, Cambridge, 13 May 1933.
4. ↑ JB bottom of 359.
5. ↑ JB 340.
6. ↑ JB 340.
7. ↑ JB 360. W. Caland and V. Henry in their *L'Agniṣṭoma*, beginning on p. XI of the Preface, describe the function of the various priests and say of the first Priest the following:

    > Le prêtre dit *brahman* occupe une place à part. En principe, i est muet et inactif, et pourtant il passe pour le personnage le plus important du drame qui se joue sous ses yeux impassibles. Il est le 'médecin du sacrifice': si quelque manquement s'y est produit, il sait le rite et la formule efficaces qui en annulent les conséquences; il accomplit le rite, profère la formule et *rentre dans son repos*. [Italics mine]

    And so the priest who ranked first in importance had virtually nothing to do! He remained in his place and then withdrew 'to take his rest'. The brilliant men who composed *L'Agniṣṭoma* were working from sources composed after the use of the Soma-plant had been abandoned. Was not this 'first priest' in line of succession to a priest who, in the days when the genuine Soma was present, had been singled out to drink the Soma and then to retire into seclusion and pass into a state of rapture - what Brough calls a 'stupor'? Vedic students should examine carefully the sources to see what additional light they shed on this first of the priests, who thus went off to *prendre son repos*.
8. ↑ I regret that I confused Brough with my presentation of the Vogul tale, to which he draws attention, JB 360. The two recensions of the Epic song 'about the creation of the heavens and earth', Reguly's and Munkácsi's, taken down 40 years apart, differ only in minute linguistic details that do not affect the meaning. The translation of the song was never in question, only the accuracy of Munkácsi's summary, which is printed in italic in my SOMA, pp. 307-308, and I went to Budapest to consult János Gulya for this purpose. It turned out that Munkácsi's summary was grossly inaccurate.

IV

Was There a Soma-urine?

As an inebriant the fly-agaric possesses a property that is peculiar to it: the potency in this mushroom passes through to the urine and the urine is as inebriating as the mushroom itself, possibly more so. Perhaps the Indo-Iranians made no use of this property, or made only occasional use of it when there was a shortage of the original plant, or they may have resorted to the urine in some areas and not in others, or they may have practiced urine-drinking early in the Vedic age and then abandoned it. But even if the Indo-Iranians never resorted to Soma-urine, if in the Vedic age they showed knowledge of the inebriating quality of the urine after imbibing Soma, this alone would suffice: it is proof - and what proof! - that we have identified the plant. It would rivet the superb fly-agaric to the Divine Soma. For the fly-agaric, so far as we know, is the sole source of muscimol, and muscimol, so far as we know, is the sole hallucinogen that passes through to the urine with unchanged potency.

I do not assert that the Vedic priests drank Soma-urine. I say the case for the practice is strong and cannot be dismissed out of hand. The intense repugnance of the West and among occidentalized Hindus to my idea is only an anthropological trait of Westerners and we must guard against being swayed by our tribal traits. A knee-jerk rejection tells more about us than about the Indo-Iranians of old.

As with vomiting, the attitude in the East toward urine is different from ours. Urine is extensively used as medicine and in ablutions and in certain religious offices. Urine is normally the chief source of sterile fluid available to peoples who do not possess our technology, especially useful for washing wounds.

In a Gatha of the Avesta, Yasna 48.rn, Zarathustra excoriates a practice of the priests:

> When will you (O Mazdah) do away with the urine *of this drunkenness* with which the priests evilly delude the people? [Italics mine.]

It seems to me that Zarathustra was speaking of the Haoma-urine drinking in the ritual. F.B.J. Kuiper, who disagrees with me on my identification of Soma, is nevertheless cautious in his comment on my interpretation:

> Since there is ample evidence to show that the fly-agaric can also be 'taken in the urine of the person who has ingested it,'... the surprising novel interpretation of Zarathustra's words... may well contain a grain of truth,... [*Indo-Iranian Journal*, Vol. XII No. 4 (1970) p. 283]

But now listen to Brough:

> It seems certain that Zarathustra here is castigating the Haoma-ritual; but there is no reason to see in the word *m&umacr;θra* anything more than a strong term of abuse... [JB 348]

But was 'piss' a term of abuse in ancient Iran, let alone a strong one? Brough produces no parallel texts citing 'piss' as a term of abuse, not from the Avesta, nor from Sogdian or Khotanese sources, nor from the corpus of Pahlevi writings, nor from the vast body of Vedic and Sanskrit texts with which he is familiar. He produces none at all and I doubt whether he can. He would ask us to accept a usage probably running counter to Iranian attitudes that would be a *hapax*, rather than the plain meaning of the verse. He would conjure away a crux with a bland assertion! Let us note that our text speaks of the *urine of this drunkenness*.

It is my suggestion that the 'third filter', mentioned twice in the *ṚgVeda* (IX 73.8, 97.55), is the human organism filtering the Soma juice through to the urine. Abundant testimony from travelers, anthropologists, linguists, and others sheds light on the practice as it has survived down to our times among the most remote peoples in the northern tier of cultures in Siberia, the Paleosiberians, and also some of the Uralic tribes - the Samoyed, one branch of the Lapps, the Ob Ugrians, and possibly some of the Finnie peoples. The urine-drinking custom is strong among the Northeastern tribes in the Chukotka. These facts are challenged by no one, no matter how surprising they are to Westerners coming upon them for the first time. It is the thesis of my book that a practice, amply attested in modern times for northern Siberia and Europe, was shared in the remote past by the Indo-Aryans who brought it down from their northern homeland, a plausible thesis that needs to be weighed, rather than rejected out of hand. Brough proffers no explanation for the 'third filter'.

Here is what Claude Levi-Strauss in his review article on my *SOMA* (*L'Homme*, Vol. 10, No. 1, 1970, p. 9) had to say about my construction of the 'third filter':

> Quant au troisième filtre, sa nature et son rôle demeurent inexplicables, sauf à y reconnaître le corps même du consommateur... à travers lequel le Soma passe en se clarifiant pour rejaillir sous forme d'urine. Il est de fait que de nombreux versets prêtent une extrême attention au cheminement du Soma clans l'estomac, le ventre et les entrailles du dlieu.

After dismissing cavalierly a series of Vedic verses discussing Soma in the enormous belly and the entrails of Indra, Brough concludes:

> ... there is no hint in the RV that Indra ever excreted *soma*. [JB 359]

Brough overlooked VIII 4.10:

> Like a thirsty stag, come here to drink;
> Drink Soma, as much as you wish.
> Pissing it out day by day, O generous one,
> you have assumed your most mighty force.
> (Tr. by Daniel H. H. Ingalls)

How does Brough render this verse? Until we hear from him, there stands Indra with his vast belly full of Soma daily pissing Soma.

And in II 34.13 the Rudras in the shape of horses seem to have pissed Soma. This is certainly a possible construction of the verse.

When one drinks tea or coffee or milk or beer, one urinates not tea or coffee or milk or beer, but urine. Why does Indra, why possibly do the Rudras, urinate Soma? How did the Vedic priests learn about Soma-urine unless they had drunk it?

Among the hallucinogens known so far to science, the fly-agaric is unique in that its active agent - muscimol - is carried through to the urine unchanged.[1] If Indra pisses Soma, as he does, what can he have drunk other than the pressed juice of the reflated fly-agaric? How else is Soma-urine to be explained? This reminds me of Voltaire's apophthegm: *Si Dieu n'existait pas, il faudrait l'inventer*. With Soma-urine the opposite holds true: *Si cela n'existait pas, qui pourrait l'inventeri*?

As for Brough's discussion of IX 74-4, he says that Geldner's conjecture making the priests piss in the ritual seems 'not impossible', though for him it is 'highly improbable'. Geldner's conjecture is all the more remarkable in that he did not, when he made it, suspect the possibility of Soma-urine. What would he have said now that I have introduced the fly-agaric? Brough accepts Renou's rendering of *náro* in this verse as referring to the Maruts:

> '... the presence of the Maruts in this verse is beyond dispute.' [JB 347]

But Daniel H. H. Ingalls a year earlier had already disputed this finding of Brough's. Ingalls, who rejects my Soma-urine theory, had declared in April 1970 that I had 'been sharper than most Vedic; translators in seeing that the word *náro* in that verse must refer to the priests. It must;...'[2] Ingalls and Brough disagree with each other and with me on the interpretation to be given to this whole passage.

In later times we find references to Soma-urine and the drinking of it. According to a well known Br&amacr;hmaṇa story[3] Indra drinks so much Soma that it flowed out from all of the orifices of his body *as well as from his bladder*. In the Mah&amacr;bh&amacr;rata there is a quaint apologue,[4] a late interpolation, telling how a *m&amacr;tañga* (lowest of the low) invited the holy man Uttañka to drink his urine to quench Uttañka's unbearable thirst and how Uttañka, feeling insulted and indignant, refused the proffered beverage, only to learn later that the *m&amacr;tañga* had been Kṛṣṇa in disguise who had been offering him *amṛta* urine. *Amṛta* is often used in the *ṚgVeda* and the old texts as a synonym for Soma. These are telling citations difficult for even the most determined exegete to conjure away. Brough fails to mention them.

There is more evidence, remote but nonetheless enlightening. The Parsis, descendants of the Zoroastrians, to this day consume urine in their religious devotions, though only in symbolic amounts and only bull's urine.[5] The Manichæans, whose religion was an off-shoot of Zoroastrianism, exercised considerable influence in China for some centuries and from a late date in Fukien Province there survive two reports by a high civil servant to his superiors of the Chinese Establishment criticizing the religious activities of those Manichæans sectarians. In their devotions, he said, they consume too many *red mushrooms* and moreover they were making use of urine, apparently human urine.[6]

If my interpretation of the *ṚgVeda* in the matter of Soma-urine meets with resistance in the West, in India in some quarters it has proved acceptable, even illuminating. A lady of English origin writes me that she was in a circle of Indian ladies and one of them, a ranee, was expatiating on the infatuation of her husband, the rajah, for a certain *s&amacr;dhu*. Why, he even wishes to drink the *s&amacr;dhu*'s urine, she said. The Indian ladies accepted this calmly, as though not surprised, and my correspondent therefore remained silent. Again, an Indian intellectual says that the present-day *s&amacr;dhu* conveys his spiritual powers to his disciples in any one of four ways: 1) by a 'laying-on' of hands, precisely as in our Church; 2) by having his disciple repeat incessantly for long periods a certain *mantra*; 3) by having him fix his gaze undeviatingly on the *s&amacr;dhu*'s countenance for long periods; and finally 4) by giving his favoured disciple the privilege of drinking his urine. I think these instances of contemporary urine-drinking may come down from the time when urine was still impregnated with the essence of Soma.

Sometimes I am asked why, if there was Soma-urine in Vedic times, it is not more specifically described: the Brahmans in those remote days were certainly not squeamish about the bodily functions. True, Victorian squeamishness was foreign to the Aryans. Our sole source of information about this practice is the body of hymns known as the *ṚgVeda*. The hymnologists composed their verses for other Brahmans and themselves to chant and hear, and their audience of course knew all about the practice. We are fortunate that there should be two direct references to the Third Filter, and a number of oblique allusions. There must have been a reticence, not from squeamishness, but from a sense of holiness that attended the miracle of transubstantiation when the urine of the priest became the divine Soma, to the accompaniment of the liturgy and hymns rendered with careful perfection. A Holy Mystery always and everywhere leaves the devout believer reticent, as he sings and acts out the canon of the liturgy in awesome measures... Transubstantiation! How surprising are the parallels between certain features in the Soma sacrifice and the heavy burden of centuries of Christian theology!

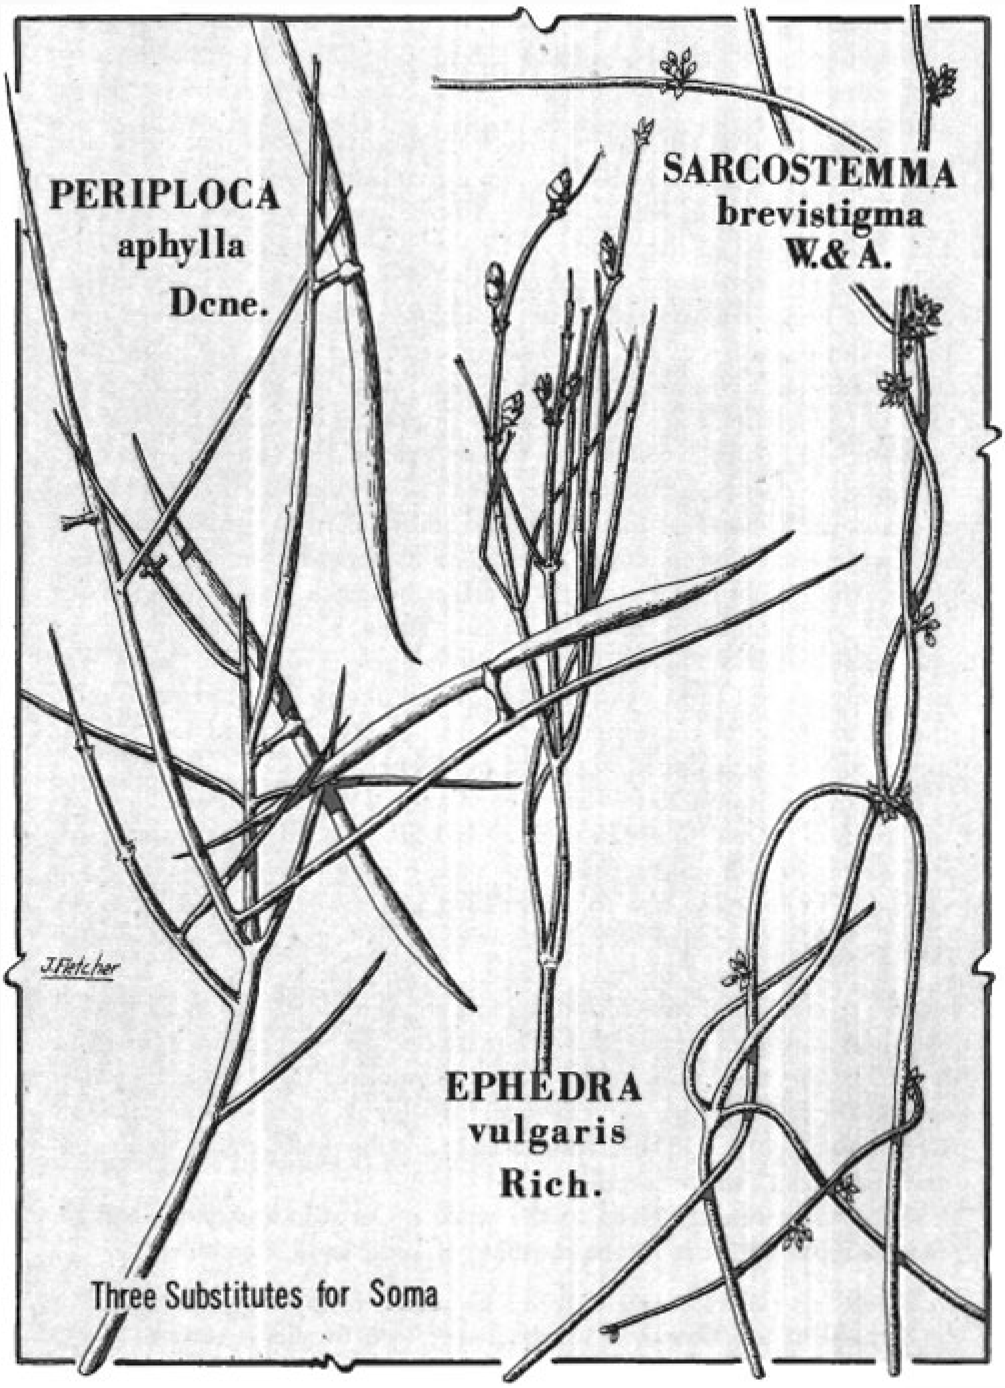
Questions of Exegesis

Brough advances, tentatively it is true, the hypothesis that *aṃ&sacute;ú* was the name of the Soma plant. We agree that Soma was a god and that *pávam&amacr;na*, the juice of the plant, was worshipped as a god. I would consider that the god on the mountain heights was immanent in the plant's juice, and this immanence continued after it was gathered, as it was drying and was being transported to its destination where the sacrifice took place, during storage, and after being expressed from the plant and before and after filtering. Whether 'Soma' was the name of the plant or was applied to it by metonymy is important but need not for the moment detain us. I will revert to this toward the end of my paper.



Three Substitutes for Soma

That the Vedic priests should have had two or more names, in addition to many metaphors, for their great god Soma seems to me natural, even inevitable, each of such names having had its genesis in one aspect of the plant. The names in time would overlap, but each would retain, so to speak, its own center of semantic gravity. 'Soma' grows in the mountains and upland valleys: this is its home where it reigns supreme. 'Soma' was used only on the most exalted plane. *Pávam&amacr;na* is the expressed juice, the liquor ready for consuming. *Aṃ&sacute;ú*, Brough says, is a third name: what aspect of the plant did it originally represent?

Perhaps the Brahmans felt the need of a word free of the portentous associations of 'Soma' to use in their daily round for the dried, shriveled, lacklustre globs of fungus that were their constant preoccupation. *Aṃ&sacute;ú* extended its meaning also to the pressed juice: *vide, e.g.*, VI 71.2; IX 86.45, 91.3, 96.8 and 97.14, where the sense of *aṃ&sacute;ú* overlaps that of *pávam&amacr;na*.

But the etymology of *aṃ&sacute;ú* remains as obscure as ever and is it not useless to speculate? Its Avestan cognate sheds no light and in the rest of the Indo-European languages no cognate has yet been found. Moreover, we know the word only in the sacred hymns and the Avesta. Its use, if any, in the lay language of Vedic times is a blank. Darmesteter and later Renou used *tige* for it in their translations; and Bartholomae, in his dictionary of Avestan, 'tender shoot'.

From the meanings given to the word in 'later Indo-Aryan', Brough, though rejecting 'fibre' as the meaning of Vedic *aṃ&sacute;ú*, concludes:

> ... the later development of such a meaning strongly suggests that the Soma-plant was fibrous or stringy, rather than the fleshy texture of a mushroom. [JB 338]

But the later Indo-Aryans had before their very eyes the fibrous, stringy plants that passed for Soma, for the Brahmans had selected surrogates for the genuine Soma following the Vedic era. Even today there are countless Brahmans who will solemnly tell you that the original Soma was one of these surrogates, most of them *Somalat&amacr;* or *Soma-vall&imacr;*. I urge the reader who is seriously interested in these matters to read Part II of our *SOMA* by Dr. Wendy Doniger O'Flaherty to inform himself on this extraordinary chapter in cultural history. The descriptions of these plants are insufficient for us to identify them. The earliest identifiable surrogates are species of Sarcostemma or Periploca or Ephedra, of which we carried a picture in our *SOMA* on p. 105, here reproduced on the facing page. They are indeed 'fibrous' and 'stringy', and might even have given rise to the meaning 'ray' that *aṃ&sacute;ú* also carried in later times. I think that the most learned and intelligent of the Brahmans must always have known these plants were only surrogates, but the changelings seem to have been generally accepted. There may well have been other substitutes in the beginning, and rhubarb has been suggested as one of them. To all of them 'fibrous' and 'stringy' are appropriate.

Under these circumstances in post-Vedic times, with 'Soma' surrogates aplenty at hand and accepted as the genuine article, who would think of running the movie backward for centuries, even millennia, in quest of a plant that no one living knew anything about? Here is indeed a case where the Law of Parsimony imposes itself.

Soma was the pole-star of the hymns of the *ṚgVeda*. Its abandonment must have been a momentous event in the lives of the Brahmans. Not once do the Br&amacr;hmaṇas describe the original Soma. Not once do they say that the surrogates (which they *do* describe *as surrogates*) resemble the original Soma. This consistent silence about the original Soma must have had a meaning. Negative evidence is usually weak evidence but in this instance the silence is deafening and so for once the negative evidence becomes positive. The Brahmans were masters of the mnemonic techniques - and what masters! - needed to preserve what they wished to preserve in their culture. To have preserved the memory of Soma would have been child's play for them. Did not the Brahmans hope, did they not feel (and in the event rightly so), that later generations would assume the original Soma was in some way similar to the surrogates? Here in Soma is an example of successful priestly obfuscation on the part of the Brahman custodians of the secret - successful down to our own day. (The Brahmans must have had their own good reasons for acting as they did.) Professor Brough himself attributes to the original Soma the properties of the surrogates![7]

★

Now I quote from Brough's paper, to illustrate the nature of his exegesis

> '*Soma grew in the mountains.*' This is important for the fly-agaric theory, since the plant grows only in mycorrhizal relationship with the birch and (less frequently) conifers. 'In northern Eurasia the birch and conifer grow at sea level. South of the Oxus and in India they are found only at a great height in the mountains, around 8,000 to 16,000 feet'... This would account for the increasing difficulty in obtaining supplies of the plant as the Indo-Aryans penetrated further south. The implicit syllogism is obviously invalid, by reason of the undistributed middle: at this point in the argument, many other plants growing in the mountains may still be considered possible. The twelve RV verses quoted here by Wasson show only that Soma (but plant or god?) was located on the mountains. [JB 342]

'The implicit syllogism is obviously invalid.' But I *implied* no syllogism. What I meant I wrote, nothing more. Brough *inferred*, mistakenly, an invalid syllogism and would father it on me.[8] Who could suppose me such a simpleton as to assert that Soma and the fly-agaric are identical because they both grow in the mountains? In *SOMA* I developed successively a number of propositions each of which served to limit the area of search for Soma. For an example, the poets insistently place Soma in the heights: ergo, we exclude the lowland flora. I pointed out, step by step, how Soma and the fly-agaric shared in these successive attributes. Instead of a faulty syllogism on my part, we are offered a faulty inference on Brough's.

★

The twelve verses that I quoted in *SOMA* indeed show that Soma, both plant and god, dwelt in the mountains, as Brough concedes.

Then Brough goes on to quote two verses where the poets have referred to Soma as growing also in valleys, as though valleys had of necessity to be close to sea-level and lofty valleys were a rarity. True, Brough may be thinking of the Cotswolds and the Grampians, but we are not speaking of England or Scotland. We are speaking of the Hindu Kush and the Himalayas where mountains rise from the hot plains quickly to great heights and where valleys start at the hightest level. Mountains and valleys go together; they are the recto and verso of a page, the observe and reverse of a coin. When the composer of Yasna 10.17 spoke of 'the Haomas whether those on the heights of the mountains, whether those in the valleys of the rivers', was he not resorting to the familiar poetic device of parallelism, saying the same thing in different words? And where in *ṚgVeda* VIII 6.28 the poet speaks of 'the hidden place of the mountains, and in the confluence of the river's', he is surely referring to the celestial counterpart lying in the heavens.

> It is difficult [says Brough] to imagine that the ritual utterances of the ceremonies of Soma Pavam&amacr;na... should be dominated by rapturous descriptions of *A. muscaria*, a plant which can be seen in its beauty during only a few days in the year. [JB 335]

Why is it difficult? The difficulty lies rather in imagining the opposite. When the whole of the religious life of the Brahmans was centered on this miraculous plant, when the Brahmans were constantly preoccupied with assuring a regular supply of it, when it evoked overpowering awe and reverence among them, could they be heedless of its provenience? Of its life-cycle? That it was visible for only a short time in the year in places perhaps inaccessible to all but a few of the priests would create for the glowing plant a scarcity value, enhancing yet further its unique status in the world's order. They were not living in our segmented culture, many of us shut off from all-providing Nature, the umbilical cord to Nature severed. They were living in a sparsely settled countryside. They were doubtless great walkers as the Hindus are today. They lived close to nature. The harvesting of the Soma-plants must have been the occasion for special ceremonies and holy rejoicings, all perhaps ordered according to the movements of the sun and moon, as was and still is the case in Mexico when 'God's flesh' (the inebriating mushrooms) is gathered on the mountainside just before sunrise. But we know nothing of this: the abandonment of Soma meant that any ceremonies proper to its gathering lapsed. When Soma at last came to be abandoned, the difficulties in the way of achieving this drastic, this revolutionary, step must have been greatly eased by two facts: first, the Brahmans alone were custodians of its secrets, and, second, certainly only some of the Brahmans knew the plant *in situ*, growing in the mountains.

If I understand Brough, he thinks that the poets' interest in the Soma-plant began only when someone else delivered the dried plants to them in the lowlands. Are there those (other than Brough) who can believe this? I cannot.

Brough performs a similar feat in dismissing the poets' failure to mention the roots, leaves, blossoms, fruit (or seed) of Soma. He thinks it natural for scores of poets over generations or even centuries, in different religious centers, to sing of the holy plant, focus of their religion, without a single one of them mentioning these indispensable organs of the phanerogams. This omission does not strike him as in the least surprising. It is my position on the other hand that these parts of ordinary plants failed to be mentioned *because a mushroom does not possess them*.

★

The Colour of Soma. When I returned from the Far East in the winter of 1965-66, I spent the thirty-five days of voyage on a freighter drafting a 31-page *précis* of my argument. I also drew up a list of questions to put to those who knew the *ṚgVeda*. My *précis* with illustrations went to Louis Renou in Paris. I followed a few weeks later with my questions. The most important one, as important as all the others put together, was whether *hári* was incompatible with the fly-agaric. I put the question to Renou at our first meeting and discussed it thoroughly again when I was spending Sunday with him in the country, right after Easter of 1966. He had already seen, of course, my principal photographs that accompanied the *précis* and that were later published in *SOMA*. Brough asks on what evidence the two sentences that he quotes from me were based. Those sentences read as follows:

> *Hári* is not only a colour word: the intensity of the colour is also expressed by it. It is dazzling, brilliant, lustrous, resplendent, flaming. [JB 349]

They were the judgement of Louis Renou. The wording is mine, the substance was his. It was I who raised this point, being sceptical about the applicability of *hári*. It was Renou's idea that the intensity of the colour might have been the common denominator linking the fly-agaric with the sun and fire. He developed his thinking on this at some length and delighted me with his illuminating exposition. In many languages there is one colour word that carries a further meaning of superlative intensity, of ultimate enhancement, *etc.*, a meaning independent of its position in the spectrum.

The horse was the noblest of domesticated animals, full of brio and fire, and among horses the bay was outstanding. What could be more natural than that 'bay' would serve as the adjective to express what the sun, fire, the steed of the sun-god, and the fly-agaric possessed in common, a superlative intensity in colour? In Appendix III c we cite an instance of such a word in circumstances not unrelated to the point at issue here.

We are discussing poets, not spectrum calibrators, not exegetes. The Vedic poet would feel the need of a word to characterize the glowing scarlet of his mushrooms, a *mot juste*. He saw, he chose to see, he arrived at a convention to think of the sun, fire, the steed of the sun-god, the fly-agaric as equally flaming, resplendent, lustrous, brilliant, dazzling: as sharing in these supreme qualities. Soma and the sun and Agni were all-important in his world. The poets saw them as in a class by themselves. Other poets will quickly grasp this, and also poets *in posse*, among whom will be found some exegetes, including in the end I hope John Brough.

★

On this question of the meaning of *hári* Brough says that 'red is absolutely excluded'.[9] He is as sure of this as he was of the Maruts whose presence in IX 74:4 was 'beyond dispute' only to be confronted with Ingalls who had already, a year earlier, disputed their presence.

I have made no effort to find a plant that would fit the preconceptions of any one Vedist. I have chosen a plant that I think can be reconciled with the *ṚgVeda*, let the chips fall where they may. It is incumbent on Vedists to see whether, even at the price of revising their previously held individual views, my solution is compatible with the *ṚgVeda*. Many Vedists are taking their time with my *SOMA*: they are living with my idea. They may come up with a hard core of objections and the fly-agaric will then pass into the lumber room of discarded notions. But everything of worth that has turned up so far since my *SOMA* appeared has in fact buttressed my case.

The identification of Soma calls for a rationale of its own. If we were privileged to travel on H. G. Wells's time machine, we could all ride together backward in time and there in the mountains of northwest India confront the plant Soma. The sight would resolve innumerable doubts with clean finality. Not possessing a time machine, however, we must stand before every candidate and see whether it can be reconciled with the *ṚgVeda*. It matters not at all if there have been two or more interpretations to a given verse, *provided one interpretation fits the candidate*. For example, when the poet speaks of 'valleys' as a home for Soma, meaning perhaps lowland valleys, this is irrelevant, if the poet could have had in mind upland valleys. And does the candidate shed light on words and expressions heretofore obscure? Or wholly new readings may be suggested by the fly-agaric... Our quest is an obstacle course, and every obstacle overcome means a substantial gain and an accelerating achievement, until we face virtual certainty.

★

Of my plates VII and IX in *SOMA* Brough says [JB 353-356] that they are 'among the most visually persuasive for Wasson's theory'. We are discussing the Vedic lines, 'He makes of milk his vesture-of-grand-occasion' and 'The hide is of bull, the dress of sheep'. But Brough says my photographs are ruled out as evidence because I must first prove that the fly-agaric is Soma before they qualify. He is reverting here to the rule that he lays down in his opening pages and that I reject as untenable. We all know of many valued discoveries, in humane letters as well as science, that have been made following precisely this procedure, reaching out and discovering analogies, exploring further, finding additional parallels, in the end establishing the case for which proof was being sought.

The *ṚgVeda* IX 97.9 says that 'by day he [Soma] appears *hári*, by night, silvery white.' Brough finds [JB 352] my photographs illustrating this verse 'charming' but says they will not do. He prefers Geldner's comment: *Soma als Sonne und Mond*. I submit that it is questionable for the exegete to cite Geldner as an authority when Geldner did not have before him my alternative reading. How does Brough know that Geldner would hold to his view today? (Let us not forget that Geldner, *unaware of my Soma-urine theory*, went so far as to suggest the possibility that the priests piss in the course of the rite!) Or perhaps Geldner would accept both readings, the Vedic poets being eminently skilled in expressing two planes of meanings with the same words. We must remember that Soma as the moon figures overwhelmingly in post-Vedic, Brahmanical times, and that this conception in the *ṚgVeda* is of disputed strength, especially if we eliminate from consideration the last batch of hymns to be admitted to the canon. Geldner's rendering may well be an out and out anachronism. He may have resorted to it for want of a better explanation. I have sometimes asked myself whether the moon as 'Soma', rather than as *candrámas*, was associated with the abandonment of Soma, when the translation to the skies of this divinity was a happy solution for the problem of Soma's disappearance here below.

★

I will finish this section with a question. Do we not find in the fly-agaric a happy solution to the identity of the Vedic divinity, Aja Ekap&amacr;d? Already in the last century Abel Bergaigne was saying that this meant the *Non-né Unipéde*, 'the Not-born Single-foot',[10] but he was at a loss to explain this curious name. Now we see what was meant. The god Soma has a single foot and he is also 'Not-born', for the herbalists of old knew well that mushrooms have no seed and come into being, not like all other creatures, but springing up mysteriously, children as they thought of the gods. (In those days there were no microscopes to reveal the spores.) There is a verse in the *ṚgVeda* that says Parjanya, the god of thunder, was the father of Soma, and according to another verse, 'the gods, those fathers with a commanding glance, laid the Somic germ'.[11]

Bergaigne showed noteworthy prescience in divining the sense of Aja Ekap&amacr;d, groping blindly as he was; and so did Geldner when he surmised that the priests might be pissing in the course of the ritual, though he knew nothing of the fly-agaric or muscimol.[12]

In the *ṚgVeda* the full name of Aja Ekap&amacr;d is cited six times, always in hymns to the Vi&sacute;vadevas, and accompanied in five of the citations by another divinity, Ahi Budhnya, the serpent of the depths, a chthonic being who invariably guards the holy plant throughout Eurasia. That Aja Ekap&amacr;d is another name for Soma, perhaps already archaic in Vedic times, finds support in RV X 65.13, where the epithet proper to Soma, 'Mainstay of the Sky', is applied to him. Pliny[13] tells us of a single-legged folk (*monocoli*) said to live in India who take their siesta in the shadow of their own single foot. Is not this the Vedic personification of Soma, Ekap&amacr;d, which by the time it reached the Mediterranean 1000 years later had become confused with a genuine people, and is not this fabulous folk revealingly linked in Pliny's text to a *chattra*, a parasol mushroom? In RV X 82.6 Aja appears, not now linked to Ekap&amacr;d, but to the navel, *n&amacr;bhi*, and thus two seemingly disparate metaphors are reconciled in the divine mushroom, both referring to Soma. Even more exciting, at the far end of Eurasia, is the myth of the Chukchi to explain thunder.[14] The Chukchi live in the peninsula known as the Chukotka, opposite Alaska. They are linguistically related to the Koryak and the Kamchadal. The Russian anthropologist V. G. Bogoraz reports that thunder is

> the rattling noise made by girls [the 'fly-agaric girls' of Chukchi parlance] playing on a spread sealskin. Rain is the urine of one of the girls. In one tale the lightning is described as a one-sided man [a 'Uniped', *monocolus*] who drags his one-sided sister along by her foot. She is intoxicated with the fly-agaric. The noise caused by her back as it strikes the floor of heaven is thunder, her urine is the [Soma-impregnated] rain.

In this myth we find the same forest-belt themes as in the Vedic hymns - Ekap&amacr;d (him of the single foot), the fly-agaric inebriant, with the thunderstorm complex and the Soma urine.

1. ↑ The Eugster-Waser team ignored the Siberian experience but Peter Waser in a paper published in 1967 (No. 10 in Appendix I, pp. 437-438) made known that muscimol, the most important psychotomimetic so far discovered in *A. muscaria*, passed through to the urine. Once again his finding confirms what the tribesmen have known for ages from personal observation. Richard Evans Schultes drew attention to this convergence of herbal lore of the tribesmen with contemporary scientific discovery in his paper published in the *Journal of Psychedelic Drugs*, Spring 1971, Vol. 3, No. 2, p. 105.

This last citation is a scholiast's effusion carried to absurd lengths, but it raises an interesting question. The muscimol in the dried and reflated fly-agaric passes through to the urine, but does it also come through in the secretions of the sweat glands and tear ducts? The pharmacologists and chemists must answer this and it can easily be answered. If we found muscimol in the sweat and tears of those who have ingested the juice of the reflated fly-agaric, it would mean that the *ṚgVeda* had called our attention to something we did not know about the hallucinogenic *Amanita muscaria*!

7. ↑ In his discussion of *aṃ&sacute;ú* Brough has this curious sentence that I call to the reader's attention:

   > There are no grounds for believing that the Indo-Iranians were sufficiently skilled herbalists to have made such discoveries. [JB bottom of p. 336]

   On the contrary there is every ground for so believing. The Indo-Iranians, not advanced like us technologically, must have been skilled herbalists like all other peoples at their stage of development. They lived in intimate contact with nature. They knew their plants: which to use for what illnesses and accidents, and whether the roots or the bark or the leaves or the blossoms or the seed, and how to prepare and apply the medication, whether externally or by ingestion, and the dosage, *etc.*, *etc*. True, we know this chiefly by analogy with peoples living today in conditions similar to theirs, but the evidence is conclusive. Our alert pharmaceutical enterprises listen with respect to what the unlettered old woman in New Guinea or the upper Amazon or Mesoamerica or India has to say about the herbs known to her, hoping always (and sometimes with success) to learn of some new Rauwolfia. The vast herbal lore of ancient India survives, however obscurely for us, in the compilations of Caraka and Su&sacute;ruta. It survives to this day, passing from one generation to the next by word of mouth, and is a resource that has scarcely been tapped by students of economic botany. To assume a condescending attitude toward this fund of empirical knowledge of botany is grievously wrong. The *ṚgVeda* is filled with herbal lore and one hymn, X 97, is devoted to plants, *óṣadhi*. One does not ordinarily look to a collection of hymns for herbal medicine and is it not noteworthy how frequently plants are cited?

8. ↑ Here is the important though not the only *lapsus* on Brough's part. There are others. A few lines earlier he speaks of illustrations 'photographed from an angle which conceals' the annulus of the fly-agaric. Several of my colleagues have seen in this wording (which could have been easily changed to remove the sting) an implication of deliberate concealment. Brough's question about the annulus carries no weight. Seldom is it so conspicuous as in Poluzzi's illustration and often it has completely or almost completely disappeared. It is a flimsy discard of the organism.

10. ↑ *La Religion Védique*, Vol. III, pp. 20-25. *Aja* also carries the meaning 'goat', but Bergaigne rightly rejected this homonym here. See App. III C for a present day application of 'single-foot' to the fly-agaric.
11. ↑ IX 82.3; 83.3; also see Abel Bergaigne, *La Religion Védique*, Vol. I, pp. 172-3. When man depended for his survival on his knowledge of plants, and even after the domestication of certain plants became firmly rooted, the mystery of the generation of fungi, having no seed and not lending themselves to cultivation, was, it seems, widely known. *Cf*, *e.g.*, Plutarch's *Symposiaka*, Prob. 2, Bk. 4. ... In 1953 our Mazatec muleteer was Victor Hernández, a man who had traveled the mountain trails of the Sierra Madre Oriental all his life and spoke Spanish with grace, though he could neither read nor write, nor even tell the hour by the clock's face. We asked him why the sacred mushrooms were called in his native tongue 'that-which-springs-forth'. His answer, breathtaking in its sincerity and feeling, was filled with the poetry of religion, and I quote it word for word as he gave it:

    El honguillo viene por sí mismo, no se sabe de dónde,
    como el viento que viene sin saber de dónde ni porqué.
    The little mushroom comes of itself, no one knows whence,
    like the wind that comes we know not whence nor why.

12. ↑ Similar prescience was shown by Philippe de Félice in his *Poisons Sacrés Ivresses Divines* when he gave a surprisingly accurate description of Soma, pp. 268-9, Editions Albin Michel, Paris, 1936. To none of them - neither Bergaigne, Geldner, nor de Félice - did the possibility of the single-footed mushroom occur.
13. ↑ Quoting Ctesias: *Hist. Nat.* VII ii 23 (Loeb translation, Vol. II, p. 521). Ctesias derived the information from Megasthenes. See J. W. McCrindle: *Ancient India as described by Megasthenes and Arrian*, 1877; p. 76.
14. ↑ Bogoras, Waldemar: *The Chukchee*, Memoir of the Amer. Museum of Nat. Hist. Jesup North Pole Expedition, 1904-1909, pp. 322-323. In the English translation 'one-sided' is confusing. The Chukchi original of this, as well as Bogoraz's Russian translation, does not appear in the Russian publications of Bogoraz. In an analogous context, however, 'one-sided' appears in the Russian text as *ljudi-polovinki* rather than *odnobokij*, as one might have expected, and this would seem to mean a race of people equipped with only half of man's attributes, a human organism split down perpendicularly in the middle. This would fit the personification of the fly-agaric as a tribe of people having only one pedal extremity, only a single eye, *etc*. The Siberian tribes under tabu influences devise many fanciful names for the fly-agaric, of which this seems to be one. Pliny's *monocoli* is derived from the Greek μονόχωλος, for which 'one-sided' is given as a meaning by Liddell & Scott. A. P. Okladnikov in *Yakutia before its Incorporation into the Russian State* (McGill-Queen's University Press, 1970, p. 446) reports on the wide dissemination of tales about one-sided folk among the primitive tribes of the tundra and the northern taiga of Siberia. If I am right, we hear distant echoes of these fabulous beings, evoked by the fly-agaric working on the stone-age imagination in the Far North, in the 'Arimaspi' of Herodocus and the 'single-eye' of Soma, and also in Pliny's '*monocoli*'; and the conception finds full expression in the 'Aja Ekapad' of the *ṚgVeda*, which I would anchor to the fly-agaric of the taiga. It has been suggested that the important 'one-sided' mythic folk figuring in the mentality of the Siberian tribesmen of the north should be called 'halflings' in English.

VI

Conclusion

In his 31-page review article Professor John Brough rakes me fore and aft with grape and ball. As the smoke slowly drifts away he finds me riding the waves much as before, with a shot here and there through my rigging. His gun sights had suffered a consistent deviation from the true.

In Victorian days there was a familiar literary device: a long lost heir, vanished and since many years believed dead in the endless spaces of Australia, would turn up and make dramatic entry when all the kin had gathered around the table to listen to the reading of the will. Each of those present, in the surprise of the moment, would react according to character, and the reactions were as diverse as the author could make them. There is some analogy here with my *SOMA*. A stranger to the Vedic coterie, I have offered to Vedists a *jeune premier* as claimant to the honours paid to Soma *in absentia* for 3,000 years, a stunningly handsome plant, small, fleshy, paralleling in colour and shape those features of the cosmos to which the Vedic Brahmans paid utmost homage, an actual plant that until lately still evoked adoration and awe and fear among the Eurasian tribes of most ancient cultural lineage who dwell in the farthest reaches of remote Siberia. This plant is an hallucinogen, the dried plants being re-watered and then their juice pressed out, mixed with other fluids, and consumed. Furthermore, the ordinary urine of the drinker becomes impregnated with the god and then in turn is sometimes imbibed.

Professor Brough, eminent scholar of secure reputation, did me the honour of paying my candidate lengthy and courteous attention, for which I am duly grateful. By fiat he would dismiss *ab initio* the testimony of my photographs as irrelevant, as also the Siberian practices because they are Siberian and not Aryan, forgetting that human cultures are a seamless garment. He supposes - he *must* suppose in order that my photos be irrelevant - that the Vedic Brahmans were uninterested in the appearance of their glorious growing plant-god, uninformed about features of its appearance that bear breathtaking analogies with their conception of the cosmos. He offers us a *persona* of Soma that is a travesty, a staggering misconception of that holy being, if we are to believe our sole source of information, the hymns of the *ṚgVeda*. He would conjure away many exegetical questions, either by dogmatic pronouncement or by flitting lightly over deep-seated problems. Surprisingly, he asserts that the Indra of the *ṚgVeda* never pisses Soma-urine. He plunges ahead into matters botanical, chemical, pharmacological, and physiological where he has done no homework.

★

In the course of the past fifty years has it occurred to a single Vedist that Vedists are primarily responsible for the identification of Soma? Is any Vedist of the past fifty years aware of the upsurge of interest in psychotropic plants among botanists, chemists, and pharmacologists, and aware also of their achievements in this area, of the work in progress? And if not, why not?... It becomes imperative for accomplished Vedists to reread the *ṚgVeda* from beginning to end, not merely Maṇḍala IX nor those other passages where the poet uses the word 'Soma', and uncover places where the new identification of the plant clarifies the text, suggests fresh readings, and introduces additional planes of understanding. For, as Brough says, Soma 'permeates' the *ṚgVeda*.

Let the Vedists leave off feeding exclusively on the *ṚgVeda* and each other. Let them be on easy terms with the outside world, with botanists, chemists, pharmacologists, physiologists: with anthropologists, pre-historians, and students of religion among early cultures, living and moribund and dead. Brough's paper on every page shouts his need (unfelt by him) for those interdisciplinary contacts to which on principle he closes his eyes and ears. If the older generation of Vedists includes many for whom this expanded opportunity is disturbing, younger scholars will certainly seize on it with enthusiasm. As for the identity of the Soma plant, I am not without confidence in the results of any further enquiries. The annals of pioneering research count instances where the valid discoveries of workers outside the inner fold of traditional scholarship are initially ignored or rejected out-of-hand.

On an earlier page I promised to return to the meaning of 'Soma' and this I now do.

A few days after Renou received my *précis* and a couple of weeks before my meetings with him he wrote on 30 March 1966 a two page memorandum addressed to a *confrére* of his. He had read my *précis*. He knew nothing of mushrooms. He was taken aback, incredulous, sceptical. But toward the end of his memo he said:

> Ou alors, il faudrait admettre que la racine védique su- ne signifie pas 'pressurer' et que le mot qu'on traduit par 'tige' signifie autre chose.

With insight he had placed his finger on the crux, insofar as linguistics is concerned.

I have discussed the meaning of *tige*, *aṃ&sacute;ú*. As for *la racine védique su-*, meaning *pressurer*, which is the traditional and accepted etymology for 'Soma', perhaps never challenged up to now, it should be reviewed by an Indo-Europeanist of stature, preferably one intimate with the Indo-Iranian linguistic area. Is not the traditional etymology merely a popular etymology sanctified by age? Did it evolve at an early age, before the elements of philology were known, for the express purpose of fitting the liturgy? There was the need to dry the mushrooms, and then steep them in water again, and finally to squeeze the juice out and to consume the juice mixed with other fluids. In fact, the swollen importance that the pounding assumed in the liturgy the hypertrophy of the 'pressing' act - the thunderous pounding of the water-steeped plants - all this elaborate ritual may be reflected in the 'popular' etymology that became traditional, the ritual serving to consolidate the 'popular' etymology arrived at by paranomasia, act and word serving as resonators for each other. (By 'popular' I mean of course in Brahman circles, which alone were concerned with the ritual usage.) But in reality the word 'Soma' may have had a different origin. Is an alternative etymology available? Had Renou lived, had Emile Benveniste not been stricken, this matter would surely have been explored.

An Excursus: Early Man and Plant Hallucinogens.

V. Gordon Childe in what must be considered his valedictory[1] despaired of ever recapturing the emotions, the motive forces, that actuated Stone Age man: they were as dead as the microliths scattered around his settlements. But was Childe altogether right?

Only now are we beginning to sense the rôle of the plant hallucinogens in early man's cultural history, beginning to identify these plants, to analyze them from every angle, to perceive that over a large part of the habitable world (including of course the land mass of Eurasia) they quickened early man's imagination, stirred early man to the innermost core of his being, led him to know ecstasy and enthusiasm in the etymological meaning of those pregnant words. They were a heaven-sent relief from the perils and the hard drabness of his day-to-day chores. It is easy now-a-days to dismiss the hallucinogens as mere chemical compounds with surprising effects on the psyche, and so they are. But our Stone Age ancestor did not know this. He saw these astonishing effects as miraculous, and the plants opened portals for consulting his ancestors or his gods: gave him a vehicle to travel where he willed in time and space. Their unearthly splendor elicited the reverential awe of which Brough rightly speaks, and also fear and adoration, and the secrecy that naturally accompanies these emotions.

By reason of this veil of secrecy our 'advanced' civilization lost the identity of the plants themselves but perhaps as a reflex of those breathtaking visions we elaborated in their place solemn rites of utmost majesty, a mythology, a theology, which for centuries held us spellbound, though these lack the immediacy of the hallucinogenic experience that our ancestors knew. Our scientists are now searching for a use that the psychotropic plants may be put to, but whatever that use may prove to be, the contribution that they have already made to our knowledge of pre-history is of outstanding importance, no less than a Pisgah view of early man's cultural vision, where heaven and hell lay spread out on all sides of him. In this area of his existence we now grasp an aspect of Stone Age man's cultural life that until now eluded us. Childe's despairing summation must be qualified to accommodate our new knowledge.

We have always heard of the tantalizing Mysteries of Eleusis, of Mithra, of Orpheus, of Apollo, of countless others. But the secrecy with which they were surrounded proved an impassable barrier for us. A potion was drunk at Eleusis. What was that potion and whither did it lead? One Aristides in the 2nd century A. D. allowed us the faintest glimpse of what went on. The initiate experienced something 'new, astonishing, inaccessible to rational cognition'. And, speaking of the Eleusinian Mystery, he said:[2]

> Eleusis is a shrine common to the whole earth, and of all the divine things that exist among men, it is both the most awesome and the most luminous. At what place in the world have more miraculous tidings been sung, where have the dromena called forth greater emotion, *where has there been greater rivalry between seeing and hearing*?

And then he went on to speak of the 'ineffable visions' that it had been the privilege of many generations of fortunate men and women to behold.

'Shamanism' is the convenient name that we give to the religious experience of the Stone Age, and its key is ecstasy, rapture. Fortunately for us, the cult of the hallucinogen did not die out in pre-history. Shamanism lingered on here and there, reaching as with fingers down the corridors of time into early history. I suggest that it survives to this day in the secret rites of the divine mushroom in Mesoamerica, and also that we possess in the potent cult of Soma among Aryan Brahmans a shamanic legacy that we are only now in a position to esteem at its inestimable worth. Here was a group who when the moment came to abandon Soma, the Element in their communion, worked out mnemonic devices of incomparable strength, this strength being a measure of the potency of the hallucinogenic visions they knew well, to assure the perpetuation of the hymns they sang, words and music, so that we today may, as with a tape recording, listen in their chants to the very words and notes they sang. We do not yet know how it came about that shamanism, in this instance, passed on to a priestly class its most precious gift, the gift of Soma.

Let us remember that Soma was not born (Aja) as elements of this world are born; his birth was miraculous, conceived in the soft, fertile earth by an ejaculation of thunder and lightning accompanied with a downfall of rain. The plant-god was sacrificed in the course of the liturgy and his juice consumed by chosen men, and even by transubstantiation the urine of the priest who drank the potion was converted in turn into more of the divine fluid.

The reticence that the hallucinogen imposed on its devotees was only natural, inspired by the reverential awe that still handicaps the student of the hallucinogenic mushrooms in the remotest mountains of southern Mexico, an awe so overwhelming, a reticence so complete, that only now, after four centuries of the Spaniards' Conquest, is the outside world penetrating to the heart of the Mystery and a few are partaking of the Marvelous Herb in native rites.

I would not be understood as contending that only these substances (wherever found in nature) bring about visions and ecstasy. Clearly some poets and prophets and many mystics and ascetics seem to have enjoyed ecstatic visions that answer the requirements of the ancient Mysteries and that duplicate the mushroom agapé of Mexico. I do not suggest that St. John of Patmos ate mushrooms in order to write the Book of the Revelation. But the succession of images in his Vision, so clearly seen and yet such a phantasmagoria, means for me that he was in the same state as one bemushroomed. Nor do I suggest for a moment that William Blake knew the mushroom when he wrote his telling account of the clarity of 'vision':

> The Prophets describe what they saw in Vision as real and existing men, whom they saw with their imaginative and immortal organs; the Apostles the same; the clearer the organ the more distinct the object. A Spirit and a Vision are not, as the modern philosophy supposes, a cloudy vapour, or a nothing: they are organized and minutely articulated beyond all that the mortal and perishing nature can produce. *He who does not imagine in stronger and better lineaments, and in stronger and better light than his perishing eye can see, does not imagine at all*. [Italics mine. From *The Writings of William Blake*, ed. by Geoffrey Keynes, vol. III, p. 108]

This must sound cryptic to one who does not share Blake's vision or who has not taken the mushroom. The advantage of the mushroom is that it puts many (if not everyone) within reach of this state without having to suffer the mortifications of Blake and St. John. It permits you to see, more clearly than our perishing mortal eye can see, vistas beyond the horizons of this life, to travel backwards and forwards in time, to enter other planes of existence, even (as the Amerindians say) to know God. It is hardly surprising that your emotions are profoundly affected, and you feel that an indissoluble bond unites you with the others who have shared with you in the sacred agapé. All that you see during this night has a pristine quality: the landscape, the edifices, the carvings, the animals - they look as though they had come straight from the Maker's workshop. This newness of everything - it is as though the world had just dawned overwhelms you and melts you with its beauty. Not unnaturally, what is happening to you seems to you freighted with significance, beside which the humdrum events of everyday are trivial. All these things you see with an immediacy of vision that leads you to say to yourself, 'Now I am seeing for the first time, seeing direct, without the intervention of mortal eyes.'

And all the time that you are seeing these things, the priestess sings, not loud, but with authority. The Amerindians are notoriously not given to displays of inner feelings - except on these occasions. The singing is good, but under the influence of the mushroom you think it is infinitely tender and sweet. It is as though you were hearing it with your mind's ear, purged of all dross. You are lying on a *petate* or mat; perhaps, if you have been wise, on an air mattress and in a sleeping bag. It is dark, for all lights have been extinguished save a few embers among the stones on the floor and the incense in a sherd. It is still, for the thatched hut is apt to be some distance away from the village. In the darkness and stillness, that voice hovers through the hut, coming now from beyond your feet, now at your very ear, now distant, now actually underneath you, *hic et ubique*, with strange ventriloquistic effect. The mushrooms produce this illusion also. Everyone experiences it, just as do the tribesmen of Siberia who have eaten of *Amanita muscaria* and lie under the spell of their shamans, displaying as these do their astonishing dexterity with ventriloquistic drum-beats. Likewise, in Mexico, I have heard a shaman engage in a most complicated percussive beat; with her hands she hits her chest, her thighs, her forehead, her arms, each giving a different resonance, keeping a complicated rhythm and modulating, even syncopating, the strokes. Your body lies in the darkness, heavy as lead, but your spirit seems to soar and perhaps leave the hut, and with the speed of thought to travel where it pleases you, in time and space, accompanied by the shaman's singing and by the ejaculations of her percussive beat. What you are seeing and what you are hearing appear as one: the music assumes harmonious shapes, giving visual form to its harmonies, and what you are seeing takes on the modalities of music - the music of the spheres. 'Where has there been greater rivalry between seeing and hearing?' How apposite to the Mexican experience was the ancient Greek's rhetorical question! All your senses are similarly affected: the cigarette with which you occasionally break the tension of the night is imbued with such an aroma as no cigarette before had ever possessed, the glass of simple water is infinitely better than champagne. Elsewhere I once wrote that the bemushroomed person is poised in space, a disembodied eye, invisible, incorporeal, seeing but not seen. In truth, he is the five senses disembodied, all of them keyed to the height of sensitivity and awareness, all of them blending into one another most strangely, until the person, utterly passive, becomes a pure receptor, infinitely delicate, of sensations. (You, being a stranger, are perforce only a receptor. But the Mazatec Indians are also participants with the *curandera* in an extempore religious colloquy. Her utterances elicit spontaneous responses from them, responses that maintain a perfect harmony with her and with each other, building up to a quiet swaying antiphonal chant. In a successful ceremony this is an essential element, and one cannot experience the full effect of the rôle of the mushroom in the Indian community unless one attends such a gathering, either alone or with one or at most two other strangers.)

As your body lies there in its sleeping bag, your soul is free, loses all sense of time, alert as it never was before, living an eternity in a night, seeing infinity in a grain of sand. What you have seen and heard is cut as with a burin in your memory, never to be effaced. At last you know what the ineffable is, and what ecstasy means. Ecstasy! The mind harks back to the origin of that word. For the Greeks *ekstasis* meant the flight of the soul from the body. Can you find a better word than that to describe the bemushroomed state? In common parlance, among the many who have not experienced ecstasy, ecstasy is fun, and I am frequently asked why I do not reach for mushrooms every night. But ecstasy is not fun. Your very soul is seized and shaken until it tingles. After all, who will choose to feel undiluted awe, or to float through that door yonder into the Divine Presence? The unknowing vulgar abuse the word, and we must recapture its full and terrifying sense... A few hours later, the next morning, you are fit to go to work. But how unimportant work seems to you, by comparison with the portentous happenings of that night! If you can, you prefer to stay close to the house, and, with those who lived through that night, compare notes, and utter exclamations of amazement.

In Nahuatl, the language spoken by the Aztecs, the sacred mushrooms were and are called *teo-nanácatl*, God's flesh. I need hardly remind the reader of a disquieting parallel, the designation of the Elements in our Eucharist: 'Take, eat, this is my body... ', and again, 'Grant us, therefore, gracious Lord, so to eat the flesh of thy dear son...' But there is one difference. The orthodox Christian must accept by an act of faith the miracle of the conversion of the bread into God's flesh: that is what is meant by Transubstantiation. By contrast the mushroom of the Nahua carries its own conviction: every communicant will testify to the miracle that he has experienced. The Mazatec Indians call[3] the sacred mushrooms ^{ʔ}*nti*^{1}*xi*^{3}*tho*^{3}, 'what leaps forth', that is, what leaps into being without the measured growth from seed, *i.e.*, the mushroom. ... We now know that there are dozens of hallucinogens, each with its own potentialities, sometimes differing greatly from each other, and we have not yet determined the specific hallucinogen or hallucinogens used in Greece and the Middle East.

I find the parallels between the mushroom cult and Christianity disquieting. In both the deity is conceived miraculously, not from seed after the order of normal generation. In both the miraculous conception is effected by a ray from heaven. In one the deity is a man-god, in the other a plant-god, and the deity is consumed in both in the course of an agapé wrapped in holy mystery. In one by an act of faith the bread and wine through a Miracle of Transubstantiation are converted into the body and blood of the Lord. In the Eurasian mushroom cult the act of transubstantiation takes place when ordinary urine becomes the divine essence.

As man emerged from his brutish past, thousands of years ago, there was a stage in the evolution of his awareness when the discovery of a mushroom (or was it a higher plant?) with miraculous properties was a revelation to him, a veritable detonator to his soul, arousing in him sentiments of awe and reverence, and gentleness and love, to the highest pitch of which mankind is capable, all those sentiments and virtues that mankind has ever since regarded as the highest attribute of his kind. It made him see what this perishing mortal eye cannot see. How right the Greeks were to hedge about this Mystery, this imbibing of the potion, with secrecy and surveillance! What today is resolved into a mere drug, a tryptamine or lysergic acid derivative, was for him a prodigious miracle, inspiring in him poetry and philosophy and religion. Perhaps with all our modern knowledge we do not need the divine mushrooms any more. Or do we need them more than ever? Some are shocked that the key even to religion might be reduced to a mere drug. On the other hand, the drug is as mysterious as ever it was: 'like the wind it cometh we know not whence, nor why.' Out of a mere drug comes the ineffable, comes ecstasy. It is not the only instance in the history of humankind where the lowly has given birth to the divine.

To conclude I will quote a passage that I wrote many years ago, before I had thought about Soma; the passage is applicable, *mutatis mutandis*, in broad terms to any hallucinogen including Soma;

'If our classical scholars were given the opportunity to attend the rite at Eleusis, to talk with the priests, what would they not exchange for that chance? They would approach the precincts, enter the hallowed chamber, with the reverence born of the texts venerated by scholars for millennia. How propitious would their frame of mind be, if they were invited to partake of the potion! Well, those rites take place now, unbeknown to classical scholars, in scattered dwellings, humble, thatched, without windows, far from the beaten track, high in the mountains of Mexico, in the stillness of the night, broken only by the distant barking of a dog or the braying of an ass. Or, since we are in the rainy season, perhaps the Mystery is accompanied by torrential rains and punctuated by terrifying thunderbolts. Then, indeed, as you lie there bemushroomed, listening to the music and seeing the visions, you know a soul shattering experience, recalling as you do the belief in both Eurasia and Mesoamerica that mushrooms, the sacred mushrooms, are divinely engendered by the God of the Thunder-bolt in the fertile Mother Earth.'

3. ↑ The sign that precedes the Mazatec word is a glottal stop. The Mazatec language is tonal, and the superscript digits represent the four registered tones, '1' being the highest and '4' the lowest. '^{ʔ}nti^{1}' is a respectful diminutive that I find difficult to translate. The 'x' somewhat resembles in pronunciation English 'sh'. The 'th' is an aspirated 't'.

Manner of Ingesting the Fly-agaric among Siberian Natives

The manner of ingesting the fly-agaric among the Siberian natives is important. All sources save one say the mushrooms must be first dried. The one exception is Georgi, whose testimony for reasons that I explain (see *SOMA*, pp. 240-1) is suspect. Almost all of them say the dried mushrooms are washed down with water or in the juice of berries or thoroughly mixed with saliva before swallowing. Saliva consists chiefly of water. Some informants call attention to the thorough and prolonged mastication that precedes ingestion. This corresponds, I suggest, to the 'pounding' of Soma, already immersed in water, a feature in Vedic ritual that seems to have undergone hypertrophic development, probably for liturgical effect. Alcohol is never cited as an additive, neither among the Aryans nor the Siberian tribesmen. Many of our witnesses from Siberia are Europeans who were quick to despise the 'filthy' practices of the tribesmen, and to contrast their 'superior' vodka with the mushrooms that, to their dismay, some of the tribesmen, when asked, preferred over alcohol. Where in one or two instances they report the ingestion of the mushrooms without mentioning the accompaniment of other fluid, this is not conclusive; the drinking of water may have seemed too banal to record. Until recent centuries distilled alcohol was unknown in the Siberian North, as it was also among the Vedic Aryans. Here are the relevant texts, with the page references to my *SOMA*:

1. KRASHENINNIKOV, STEPHAN; pp. 235-236: 'Sometimes for their enjoyment they also use the *mukhomor*, the well known mushroom that we ordinarily use for poisoning flies. [*Mukhomor* = fly-agaric] It is first soaked in must of *kiprei* [*Epilobium angustifolium*], which they drink, or else the dried mushrooms are rolled and swallowed whole, which method is very popular.'
2. STELLER, GEORG WILHELM; p. 239: 'The fly-agarics are dried, then eaten in large pieces without chewing them, washing them down with cold water.'
3. GEORGI, JOHANN GOTTLIEB; p.240: 'To that end they either eat one of these mushrooms quite fresh, or perhaps drink the decoction of three of them.'
4. LANGSDORF, GEORG HEINRICH von; pp. 247-248: 'The Kamchadals gather them usually during the hottest months of July and August; they maintain that those that dry by themselves in the earth, on the stalk, and that are somewhat furry and velvety to the touch on the underside of the cap have a far stronger narcotic effect than those picked fresh and strung up to dry in the air… The usual way to consume fly-agarics is to dry them and then to swallow them at one gulp, rolled up into a ball, without chewing them; chewing fly-agarics is considered harmful, since it is said to cause digestive disturbances.'
   'Sometimes these mushrooms are cooked fresh and eaten in soups or sauces, since they then taste more like the usual edible mushrooms and have a weaker effect, so that when the mushrooms are prepared in this way, a larger amount can be eaten without harmful results. Occasionally, too, fly-agarics are soaked in berry juice, which one may thereafter drink at his pleasure as a genuine intoxicating wine. Juice squeezed from bilberries (*Vaccinium uliginosum*) is said to be most suitable for this purpose because it heightens the intoxicating effect, so that one may expect to achieve a more potent result with a smaller quantity.'
5. ERMAN, ADOLPH; pp. 253: 'Of the various ways of using *mukhomor* he said that the best was the simplest way, *viz.*, drying it, swallowing it raw, and washing it down with water. On the other hand, the Russians of Klynchevsk, who according to him pick whole packhorse loads of this valuable plant, prepare an extract by decocting it in water, and try to take away its extremely disgusting taste by mixing the extract with various berry juices.'
6. MAYDELL, BARON GERHARD von; p. 254: 'At the Paren' I also obtained some dried fly-agaric (*Amanita muscaria*), which is very highly prized among the Koryaks for its intoxicating effect. It is not eaten in the fresh state, in which it is believed to be poisonous, but always hung up to be smoked until it is shriveled and quite dry so that it will keep well. It is said to occur only among birch trees and hence is confined to a few localities, among which I heard Penzhinskoye and Markovo mentioned in particular. When a Koryak consumes the fly-agaric, he chews the dried mushroom and then drinks it down with water.'

7. DITTMAR, CARL von; p. 256: '... the *mukhomor* is only chewed, and the juice is then swallowed.'
8. JADRINTSEV, NIKOLAI MIKHAILOVICH; p. 260: '... Furthermore, the natives are passionately addicted to the fly-agaric (*i.e.*, to a decoction of *Amanita muscaria*), which replaces liquor and is also sold to merchants.'
9. SLJUNIN, NIKOLAI VASIL'EVICH; p. 261: 'The Koryaks maintain that fresh fly-agarics are highly poisonous and hence do not eat them. They are first dried for a long time in the sun and over the fire in the tent. Only then is the mushroom consumed, together with fresh water to wash it down.'
10. ENDERLI, J.; p. 262: 'At the man's order, the woman dug into an old leather sack, in which all sorts of things were heaped one on top of another, and brought out a small package wrapped in dirty leather, from which she took a few old and dry fly-agarics. She then sat down next to the two men and began chewing the mushrooms thoroughly. After chewing, she took the mushroom out of her mouth and rolled it between her hands to the shape of a little sausage. The reason for this is that the mushroom has a highly unpleasant and nauseating taste, so that even a man who intends to eat it always gives it to someone else to chew and then swallows the little sausage whole, like a pill.'
11. JOCHELSON, WALDEMAR; p. 266: 'Accordingly, fly-agaric is dried in the sun or over the hearth after it has been gathered. It is eaten by men only; at least, I never saw a woman drugged by it. The method of using it varies. As far as I could see, in the villages of Penzhina Bay, the men, before eating it, first let the women chew it, and then [the men] swallow it. Bogoraz says that the Chukchee tear the fungus into pieces, chew it, and then drink water. Sljunin describes in the same way the Koryak method of using fly-agaric. In describing the use of fly-agaric by the Chukchee and Koryak, Dittmar says that they chew it and keep the quid in their mouths for a long time without swallowing it, Krasheninnikov says that the Kamchadal roll the dried fungus up in the form of a tube, and swallow it unchewed, or soak it in a decoction of willow-herb and drink the tincture.'
12. BOGORAZ, VLADIMIR GERMANOVICH; p. 273: 'The mushrooms are usually dried up and strung together in threes, that number being an average dose. ... When eaten, the mushrooms are torn to small shreds, and these are chewed piece by piece, and swallowed with a little water. Among the Koryak the woman chews the mushroom, and offers the ready quid to her husband to swallow.'

Miscellany

A. Professor Marija Gimbutas on Uses of Fly-agaric in European Russia.

In 1961 a Lithuanian by birth and cultural heritage, Marija Gimbutas, now the renowned pre-historian, wrote me this concerning the fly-agaric in her native land:

> ... A happier use for the *raudonoji musmir&edot;* ['fly-agaric' in Lithuanian] was to add them, raw or dried, to vodka, on occasions such as wedding banquets: the effect was a curious, extremely hilarious intoxication. Before World War I orthodox Russians in Lithuania are known to have used this 'fly-agaric vodka'. Around 1905, the fly-agaric vodka was put to good use on Russian prison guards in arranging prisoners' escapes. Around 1942 the old custom was revived in the district of Vilnius: the people added the fly-agaric to home-made vodka.
> It is known that in the 19th c., or earlier, *Amanita muscaria* was exported from the East Baltic area to the north (North Russia) for the shamans as an intoxication medium. This I read myself in the books, but cannot now remember the source.

Here is the only responsible testimony that I have found concerning a customary use for purposes of inebriation of the fly-agaric in Europe. The practice that Professor Gimbutas reports cannot go back far, since *aquavitæ* was introduced into Eastern Europe only in the 16th century. Was there a synergistic action when vodka was mixed with muscimol? This remains to be determined.

The final solution to the fly-agaric mystery is held up by the heavy tabu that hangs over the ingesting of *A. muscaria* throughout our European culture area. When I ingested dry fly-agaric in the Burgholzli Clinic in Zurich, doctors and nurses stood around viewing me with ill-concealed anxiety, though I defied and defy them to cite me a single authenticated case where anyone has suffered serious ill effects from this mushroom. Roger Heim, for the past 30 years the world's outstanding mycologist, has looked through the annals of mycology and medicine in France and has not found a single instance. *A. muscaria*, the supreme 'toadstool', is often held synonymous with 'deadly mushroom' and reports have occurred frequently where the fly-agaric is credited by careless and unqualified persons with deaths caused by other mushrooms. Brough speaks of the fly-agaric as deadly, saying that *A. phalloides* is 'much more [*sic*] deadly'. (JB 353) He cites no instance of a death, properly authenticated as to cause, from the Eurasian fly-agaric. He here gives renewed expression to the ancient European attitude toward this lovely mushroom of the peculiar properties, an attitude in which fear and rejection mingle in some localities and in some contexts with a certain awe and affection - the precise syndrome of a religious tabu.

B. Official Soviet View toward Fly-agaric Ingestion.

Sometimes I am asked why we do not enlist the cooperation of Soviet anthropologists. The Soviet authorities labour under an ideological handicap when it comes to the fly-agaric, what is commonly called today a 'hang-up'. The official position is set forth in *SOMA* (pp. 337-8) when Messrs. Brekhman and Sem gave voice to the official view that no traces of the practice survive:

> The minor nationalities of Siberia and the Far East now do not use any psychoactive drugs, which have been relinquished because of radical changes in economy, culture, mode of life, and ideology of the population of this part of the Soviet Union. After the October Socialist Revolution and the establishment of the Soviet power these not numerous nationalities have embarked on a new way of historical development. Formerly backward nationalities of one of the borderlands of Russia, with the help of the Russian people and Soviet Power, passing through intermediate stages, they have soon reached the socialist phase of social development.

Even the best workers in the field in the USSR - and they are first-rate men like A. P. Okladnikov and A. F. Anisimov, seem never to mention the fly-agaric. When we bear in mind that the larch is one of the favourite hosts to the fly-agaric, how odd it sounds to read in Anisimov, retelling a Gilyak myth, the following evasive language:

> ... As he went up the river, the younger brother saw a larch, 'A thick larch rising to the very sky.' *At the foot of the larch there was food*, grown and placed there by the 'master of the larch,' unknown to the brothers. The younger brother tasted the food and took some to give to the older one. The next day the titmice brothers proceeded together to the source of the food. There they met heavenly people - two little birds, a silver and a gold one, which had descended to the base of the larch and declared themselves the masters of the food.
>
> [*Studies in Siberian Shamanism*, ed. by Henry M. Michael, University of Toronto Press, 1963, published for the Arctic Institute of North America. Pages 169-170. Italics mine.]

The marvelous food at the foot of the larch was obviously the fly-agaric.

This quotation from Anisimov's text permits us to add the Gilyak (called *Nivkhi* in Russia today) to the Paleosiberian tribes familiar with the inebriating mushrooms. Our count is complete; we have positive evidence for the other five Paleosiberian peoples still extant, and the Gilyak are the sixth and final one. ... I have learned that the Gilyak often wear a crudely carved little wooden figure, usually with one leg, suspended around their necks to ward off illness; they call it *pangkh*. Though my sources do not say so, I think this is obviously the Ob-Ugrian word for the fly-agaric, *pango*. (See, *e.g.*, *Religioznye verovaniia narodov SSSR*, vol. I, Moscow-Leningrad, 1931, p. 79.)

To make inquiries of the Soviet authorities about the present-day use of the fly-agaric might only lead to harassment of the tribesmen in the northlands.

C. The Manikin in the Wood.

I will now quote German verses that are familiar to every child (and therefore adult) born to German as his mother tongue. It is a riddle:

Ein Männlein steht in Walde	A manikin stands in the wood
Ganz still und stumm.	Stock-still and mute.
Er hat von lauter purpur	He has of purple pure
Ein Mäntlein um.	A mantle around him.
Sag' wer mag das Männlein sein	Say, who may the manikin be
Das da steht auf einem Bein?	Who stands there on one leg?

Alternative ending:

Sag' wer mag das Männlein sein	Say, who may the manikin be
Das da steht im Wald allein	Who stands there in the wood alone
Mit dem purpur roten Mäntlein?	With the purple red mantle?

Children: Glückspilz! Fliegenpilz!	Children: Happiness mushroom! Fly-agaric!

I have supplied the text of these children's verses for two reasons. We see in the use of 'purple' how a people calls 'out its name' a colour word in a special context. Purple is altogether inappropriate to describe the cap of the fly-agaric. Adopting Brough's idea and manner, we should be constrained to say that purple 'is absolutely excluded' as a colour adjective for the fly-agaric. But there in the verses stands the 'purple' fly-agaric in all his imperial majesty!

By a happy but perhaps not fortuitous chance, the answer to the question posed by the riddle:

Say, who may the manikin be
Who stands there on one leg?

is our Soma. History is punctuated by ironies, and how ironical it would be if Max Müller and his fellow Vedists, asking everybody, everywhere, what Soma was, could have found the answer, by listening to the little children playing around his feet in Germany. We can't prove it, but the riddle sounds as though it went back long before the dawn of history. The manikin of the single leg is of course our Vedic Ekap&amacr;d.

Abstract

Although the excavators of the sanctuary of the Great Gods on the island of Samothrace recognize that drinking to the point of intoxication was practiced at the Mystery, naively this has not been seen as an element in the initiation scenario. Numerous drinking cups have been found, inscribed as the property of the gods, and the ancient village of Keramidaria ('Ceramics') was devoted to the manufacture of amphorae, officially stamped as genuine provenance of Samothrace for the export of the wine distinctive of the Mystery, probably a version of Homer's potent Maronian wine of the Cyclops. That wine still existed in the Roman Period, and on the testimony of the proconsul assigned to the province, it even required dilution with eight parts water to be drunk safely. At the time of Odysseus, the rate of dilution was twentyfold. Such potent wines achieved their high intoxicating potential from the substances added to the ferment, a fact that has now been confirmed by the discovery of an intact wine cellar from Canaan, dated to the beginning of the second millennium BCE. The myth of the establishment of the Mystery, dated to the generations before the Trojan War, narrates the tale of its founder sailing like a drunken loon upon a wineskin, and similar establishments of the Mystery of the Great Gods depict a Kabeiric dwarfish Odysseus sailing upon an amphora filled with the special potion of the great sorceress Circe. This wine was fortified with a sacred psychoactive mushroom, whose antiquity can be traced back to the wolf sacrament of the Achaemenid Persians, and documented as well in Celtic lore and among the Nordic berserkers, recorded as early as the Emperor Trajan as a rite of the Dacians of Thrace, who are named as the 'People of the Wolf' and who carried the banner of Draco into battle, a serpent with the head of a wolf. The serpent is an indication of the wolf's toxicity, and the fondness of wolves for eating the mushrooms was the basis for the rituals of lycanthropy and the initiated fraternal packs of warriors. In Athens of the Classical Age, the fungal identity of this initiatory sacrament was common knowledge, obscenely parodied on the comic stage. The Etruscans carried this sacrament to the Italian peninsula and it was incorporated into the mythologized history of Rome's founding by the Trojan Aeneas as the fulfilment of the prophecy of the edible tables that would signal the site for the future city. The cult of the Great Gods involved the widespread phenomenon of the little people that materialized from the sacramental fungus as fairy creatures, using the mushroom as their tables set with dainty morsels that inspired visionary experience and of which it was taboo for the uninitiated to partake.

The Zerynthian Cave

The Mystery of the Great Gods of Samothrace was established at the site of the present archaeological remains in the seventh century BCE, and the Temple complex was greatly expanded in the Hellenistic Age by dedications from the Macedonian heirs of Alexander, the Great. Its antiquity, however, goes back at least to the mid second millennium. Originally, the rite was performed at a still unidentified cave, one of several that issue in profuse streams falling as cataracts down the steep slope of the heavily forested volcanic island, probably the one adjacent to the village of Therma, which was channeled through the site of the later sanctuary complex below it. The legendary founders of the Mystery were the Amazons, who supposedly discovered the island uninhabited and dedicated it to the 'Mother of the Gods,' well before the Trojan War. The island, however, was probably already inhabited and sacred at least as early as the Neolithic Period.

Troy itself was supposedly founded three generations after the establishment of the Mystery by a refugee from Samothrace, although his original home was said to have been Arcadia in the central Peloponnesus, and the War was fought in the third generation after its founding. Agamemnon, as mythologized history, was cited among the list of initiates. The Arcadian origin of the Mystery was elaborated as the birthplace of Hermes and his role as cow-thief, and in the tradition that Virgil followed in narrating Rome's Trojan ancestry. The Samothracian ritual preserved prayers in a pre-Greek language, perhaps a version of Etruscan, probably a dialect of Luwian, the language of Troy with borrowings from neighboring Phrygian peoples. The deities who presided over the Mystery formed a triad and preserved their ancient occult pre-Greek names as a goddess Axieros, her daughter Axiokersa, and the daughter's mate Axiokersos, where the similar prefix apparently was an honorific indication of divinity. They were loosely equated to the later Demeter, Persephone, and Hades, although Axieros was also a version of the Anatolian Mountain Mother, who was interchangeable with Rheia and later named as Cybele. If there was a fourth in the divine group, his name was Kasmilos and equated to the later Hermes. Surprisingly, the excavators of the remains of the sanctuary have shown little interest in the Zerynthian Cave and have confined their reconstruction of the rituals to the physical ruins and to the mention of bacchanalia, which they interpret as performances of drama. Although the site offers areas for viewing certain sacred events, such as sacrificial offerings, instruction of the candidates for initiation, or perhaps the recitation of a poem like the Homeric *Hymn to Hermes*, there is no proper theater, nor is there any record of playwrights. The area below the niche for the Winged Victory monument, although stepped with seats or standing tiers, looked down upon an altar for sacrifice, with no theatrical backdrop or skene, required for dramatic performances. The slightly sunken small circular area just beyond the entrance gate was not an amphitheater, and provided only a couple of narrow tiers to accommodate viewers standing in a circle.

The ancient testimony for the sacred Zerynthian Cave is indisputable. The third-century Hellenistic poet Lycophron (*Alexandra*, 1175-1180), who was a great antiquarian of obscure traditions, mentions the Cave; and its centrality to the Mystery even at this later period is shown by its depiction, complete with the issuing cataract, in the lower right of the second-century BCE marble relief from Larissa, a dedication of Danaä, portraying a *theoxénia* or 'offering of hospitality to deity,' to the 'Great Gods,' who are shown arriving as the Dioskouroi above a flying Victory (Louvre, Ma 746). The Cave was named *Zerynthos*, a linguistic formation that is clearly in a language that predates Greek, and the goddess Hekate bore it as an epithet, as did pre-Greek Thracian versions of Apollo and Artemis. The whole northern coast of the island of Samothrace was still identified with that epithet in the first century CE (Ovid, *Tristia*, 10-19). Similar Zerythian caves existed throughout the mainland of ancient Thrace. The bacchanalia, so-called, would obviously have occurred originally at these Caves, precluding the scenario for the performance of established or scripted dramas as the essential element of the Mystery. Several Hellenistic buildings in the later temple complex of the sanctuary can be interpreted as architectural simulacra of caves, being either built into an excavated hillside (like the Imperial Period *Anaktoron* lodge-hall), or like the third-century BCE Rotunda of Queen Arsinoë, the largest enclosed round building of ancient Greece, which, despite its grandeur, had a dirt floor to imitate the cave that it replaced.

Lycanthropy

The Zerynthian deities were worshipped by the offering of canines, a victim associated with the chthonic Hekate, but also involved in the traditions of Apollo and Artemis, most notably in the Corycian 'Wolf-Cave' above Delphi on Mount Parnassus, which was the well documented site of bacchanalia (Euripides, *Ion*), that were clearly not dramatic performances, but states of intense intoxication, still as late as the second century CE, as recorded by Plutarch, who was a priest at Delphi; and in the myth of the Theban Actaeon and his hunting hounds, who reverted to wolves and attacked their master as he metamorphosed into a stag when he spied upon Artemis bathing nude. Kotytto, a Thracian version of Athena, led them into battle. She was worshipped in ecstatic midnight bacchanalian drunken orgies on hilltops (Aeschylus, frag. 27), surviving well into the Roman Period in the Cotyttia Festival described by Horace and Juvenal, involving not only intoxication, but pharmaceutical lore and wild promiscuous sexual abandon (Ruck *et al.*, 2014; Horace, *Epodes*, 17; Juvenal, *Satires*, 2).

The involvement of canines is most probably metaphoric for the nature of the bacchanalia, indicating that the intoxication was interpreted with the metaphor of rabidity, the madness that links the domesticated dog with its wild canine antecedents as wolves and foxes. The rabid madness was personified as Lyssa, which designates the 'she-wolf' (Euripides, *Heracles*). The entire pelt of the red fox was worn by the Zerynthian deities as headdress, and by the Thracian bacchants, at least as late as the fifth century BCE, who took their name from the fox pelt as Bassarides (Aeschylus, *Bassarides*; Euripides, *Bacchae*). The myth of the Thracian Lycurgus, named as the 'Wolf-worker' and indicative of lycanthropy, and the Homeric account of his opposition to the Thracian bacchant maenads, suggest that the wolf represents a pre-Dionysian manifestation of ecstatic intoxication.

The fox pelt was stylized as the Thracian/Phrygian cap, imitating the pointed red snout of the animal (Ruck *et al.*, 2014). It is never worn throughout its long history without reference to the significance of its origin as indicative of lycanthropic intoxication and emblematic of initiation into religious Mysteries. Even as later awarded to liberated slaves as the liberty cap in the Roman Period, its underlying original significance symbolized the liberation from the realm of ordinary vision or transcendent altered consciousness. Most notably, the Persian Zoroastrian priests or Magi wore the cap, and it was characteristic of their mediator with deity Mithras, and it was awarded to the candidate for the highest rank in the religion of Mithraism, which spread throughout the Roman Empire, initiating most of the Emperors, soldiers, and male bureaucrats who administered the Empire (Ruck and Hoffman, 2011), until it was ostensibly ended by the Christian Conversion, although it probably was assimilated into brotherhoods of Christian knights, such as the *Ordre de la Toison d'Or* of Duke Philip the Good of Burgundy (Ruck and Hoffman, 2012). The first in the seven stages of the initiation was the grade of Raven (Corax), which was symbolized by the cup of the sacramental drink that it served to the seventh and highest rank as Father (Pater), supposedly at a banquet on the flesh of the slaughtered cosmic bull, represented by a loaf of the Raven's leavened bread, incised with the chiastic intersection of the solar and zodiacal ellipses. The cap was also worn by the legendary Perseus of Mycenae. He was the father of Perses, the name awarded to the fifth rank in the initiatory ascent of Mithraism as the 'Persian,' whose priestly title in the ceremony was the 'Keeper of the Fruits.'

Excessive Drinking

Many drinking vessels survive from the remains of the Samothracian sanctuary, leading the excavators to conclude that excessive drinking - to the point of intoxication - was an element of the initiation (Lehmann, 1954, 1998, 6th ed. 1954: 40), although they fail to see the role of a sacred potion, such as was involved in all Mystery initiations, most notably the holy *kykeon* of Eleusis. The vessels are marked as property of the Samothracian Mystery. At other sites where rituals similar to those of Samothrace were performed, considerable amounts of drinking also took place. At Thebes, the distinctive copious *skyphos* drinking cups were apparently intended to be smashed ritually after drinking the initiatory potion. Beneath the mid fourth-century BCE building in the Samothracian sanctuary euphemistically labelled the 'Hall of Choral Dancing' on the basis of a frieze of dancers linked hand-in-hand, an extensive deposit of ceramics was uncovered, dating as early as the seventh century. The Hall contained the famous sculptural group of *Aphrodite and Pothos* or 'Yearning' by the fourth-century Skopas, who may have designed the entire building. It implies the truer nature of the erotic intoxicated dancing that occurred in the Hall, and terracotta figurines from burial sites in the sanctuary represent winged Erotes (cupids) and perhaps the infant Adonis or some other version of the Anatolian goddess's young son and lover. Dances with linked hands survive as the *sirtáki*, performed at weddings and funerals, and the dance is more ecstatic than stately.

The long portico or Stoa, moreover, which after its erection in the third century BCE sheltered the initiates as they slept together overnight in the open air, cannot be divorced from the suspicion of the sexual or orgiastic experience that surrounded similar bivouacking rituals, such as the Thesmophoria in fifth-century Athens and elsewhere. It was precisely such an erotic implication that motivated the uncle of Olympias, the future mother of Alexander the Great, to send his teenage niece to Samothrace for the initiation in order to introduce her as an eligible candidate to Philip, who was looking for a new wife. Of the Thesmophoria, we know that excessive drinking was the norm (Aristophanes, *Thesmophoriazousae*, 626-633, 735-738), while the bivouacking women conversed with prostitutes or hetaerae on sexual matters and techniques as a ritual to rekindle the fire, not just that of the extinguished hearth, but also of the conjugal bed as a reuniting of the segregated sexes and the renewal of ordinary life. The relighting of the fire was apparently an element of the Samothracian rites, as indicated by the tradition of the notorious Lemnian stench and the sexual engagement of the Argonauts on route for their quest of the Golden Fleece (Burkert, 1970). The stench was a curse from Aphrodite and the volcanic forge of her husband Hephaestus and was metaphoric for the overmastering intensity of the pheromones (Ruck, 2016).

In addition, numerous amphorae from the ancient village of Keramidaria ('Ceramics') are the product of workshops devoted to the manufacture of vessels, officially stamped as genuine provenance of Samothrace. The vessels were used for export of the wine apparently distinctive of the Mystery initiation. Tradition links the wine of these Zerynthian Caves with the legendary wine of Apollo's priest Maron. The vixen, female fox-capped bacchants of his tribe of Thracian Cicones attacked Orpheus and rendered him limb from limb in their madness, an analogous tale to the death of Pentheus of Thebes, who was himself an analogue of the death of his cousin Actaeon by his maddened hounds, inasmuch as it took place in exactly the same sacred spot on the mount Cithaeron outside Thebes. (Euripides, *Bacchae*, 1291). Odysseus used this wine of Maron to intoxicate the Cyclops Polyphemus. In the Homeric account, the wine required dilution with twenty parts water to drink it safely (Homer, *Odyssey*, 9.193-255).

The Homeric narrative is modeled upon the folkloric religious motif of initiatory liberation from a cave, traceable back to caves sacred as early as the Paleolithic and fully elaborated in Plato's 'Allegory of the Cave' (*Republic*, 514a-520a) and in the third-century CE Porphyry's essay on the *Cave of the Nymphs* (Ruck, 2015). As is characteristic of an initiatory rite of passage (Turner, 1967: 93-111), Odysseus moves from his name as Nobody in the Cave of Polyphemus to his heroic identity as the 'hated' Odysseus upon emerging, escaping by the ruse of disguising himself and his men as rams. Hung upside-down beneath an animal as they emerge from the cave is a zero-point of identity. The Homeric account plays upon the two versions of the Greek for 'nobody,' the factual *oútis* ('nobody') and the potential *métis* ('perhaps nobody, somebody'), where the latter puns upon *métis* as 'clever intelligence.' It also plays upon the dialectical version as *ótis*, the childhood name of the hero as the 'floppy-eared' bear, whose long hibernation suggested the motif of spiritual renewal through cave incubation. The Etruscans knew of version of the Odysseus myth in which the hero's disappearance was caused by his becoming so sleepy that people had trouble finding him (Plutarch, *Moralia*, 2.27e). Lycanthropy and ursine transmogrification are analogous initiatory motifs (Ruck *et al.*, 2007).

A wine marketed under the name of Maron still existed in the Roman period, and although not as potent as the legendary Homeric drink, on the personal testimony of the proconsul assigned to the province, it still required dilution with eight parts water to be drunk safely (Pliny, *Natural History*, 14.53; cf. Pollux, 66.10).

Mixing the Wine

Since fermentation is limited by the lethal effect of alcohol above a certain concentration of toxicity to the fungal growth of the yeasts that convert the sugars of the juice to ethanol, such potent wines achieved their high intoxicating potential from the special admixture of substances added to the natural ferment (Euripides, *Orestes*, 497-499). Some of these substances also withdrew oxygen from the mixture to retard the further oxidizing of the ethanol to vinegar or 'sour wine.' Wine was customarily drunk diluted with several parts water, yielding a drink of low ethanol content, but fortified to varying degrees of intoxication by the adding of other psychoactive substances, symbolizing the natural intoxicants of the primordial world, before the evolution of viticulture, typically toxic vines like ivy, bryony (wild cucumber), and smilax (bindweed, wild morning glory), which mimicked the growth of the grapevine. Even deadly poisonous plants like hemlock, in sub-lethal dosages, were among the additives (Hillman, 2008: 158-159; Nicander, *Alexipharmaca*, 186-194). In the Homeric tradition, Helen notoriously added the anodyne drug nepenthes to the drink she served to her guests in Sparta (Homer, *Odyssey*, 219-221). Thus, even though diluted, small amounts of ethanol drunk over an extended period could induce severe intoxication (Eubulus, frag. 94), and Plato stigmatized the drunkenness of the symposia (Rinella, 2010).

The tradition persists in the Demotic Greek word for wine, not as *[w]oínos* or 'wine,' but *krasí* for the 'mix.' In antiquity, the wine was associated with the taste of pine sap because of the pitch smeared on the porous clay amphorae to render them watertight (Aristophanes, *Acharnians*, 190, with scholia). The resin added to modern retsina both retards the wine's oxidizing and imparts psychoactive terpenes. The discovery of an intact wine cellar from the mid-second millennium BCE confirms this ancient practice (Ritter, 2013). Whereas the wild vines and their fruits are toxic in their natural state, the leaves of the grapevine and its grapes are edible, and the grapevine, in addition, requires human intervention as annual pruning to induce it to fruit with the berries upon whose juice is grown the intoxicant as an act of civilized cultivation. The adding of natural toxins to the cultivated yielded a drink that symbolized the reconciliation of the civilized world with its wild, primordial precedents.

Herbalist Fantasies

The emblem of the bacchant fox-capped vixens was the thyrsus, the receptacle for the wild plants gathered by herbalists (Theophrastus, *History of Plants*, 9.16.2). The bacchanalia honored not the god of viticulture, but his antecedent persona. The thyrsus identifies the women as engaged in the rituals and fantasies required for picking plants imbued with animate or divine personae. The fantasies often involve motifs of sexual engagement with the creatures that materialize from the magical plants, such as is documented at least until recently in the procedures for picking mandrake in Rumania, where the women undress and present themselves seductively nude to the object of their quest (Eliade, 1985: 17). In antiquity, menses was smeared on the mandrake to entice it to release its root (Josephus, *Jewish Wars*, 7.181), or its lycanthropic madness could be averted by enlisting a dog as the actual agent to pull the root from the ground, while the herbalist kept close watch for the approach of a pecker bird who might mount a sexual attack in retaliation. Numerous vase paintings depict the sexual assault or romp of the satyrs with the bacchants, who often fend off the attack with the thyrsus aimed directly at the genitals of the ithyphallic rapists. Mystical experience is commonly interpreted as cosmic orgasm, explicitly described as such by the sixteenth-century St. Teresa of Ávila and the eleventh-century theologian Rupert of Deutz, who both imagined that they engaged sexually with the Christ (Ruck and Hoffman, 2012: 250-252). A version of such empathetic communion resulted in the numerous documented instances of the physical stigmata that afflicted mystical Christians. Dionysus also materialized among the bacchants, crossdressing as a female and presenting himself as their perfect lover. They are shown offering themselves in return, presenting him their 'bunnies,' or dancing costumed as hares, the 'bunny' (*lagós* being metaphoric for their sexual organ (Henderson, 1975: 144, 170)). The satyrs represented the wild toxins before the advent of the civilized deity of viticulture. As goat-men hybrids, it was appropriate that the goat was the animal sacrificed to Dionysus and that the goatskin was employed to house the wine grown from the fruit of the grapevine, with the neck or foot of the wineskin being its metaphoric penis.

The thyrsus as a term was interchangeable with the narthex, which has the transparent etymology of the 'narcotic receptacle or storehouse.' *Narthex* was used as the title in antiquity for various compendia of drug lore. Typically, the thyrsus was depicted stuffed with wild ivy leaves, indicating that the plants they were gathering were emblematic of the toxins of the primordial world. The ivy leaves could be replaced with a pinecone, making the wand emblematic of the transcendence accessed by the gathered herbs, since the pineal gland is so named for its resemblance to the pinecone, and it was commonly thought in antiquity to function as a third eye, the gateway for mystical vision (Galen, *On the Use of the Parts of the Body*, 8.14). The pinecone also represents the god's earlier manifestation in the resinous pine tree, commemorated in the resin added to the mixture of wine, and in such arboreal epithets of the deity as *Dendrítes*.

The ivy leaves could be imagined as dripping with honey (Euripides, *Bacchae*, 710-711), which was commonly acknowledged also as a precedent for the wine (Plato, *Symposium*, 203b), since honey, like the skins of grapes and other fruits, naturally contains the yeasts for fermentation, and when found diluted in basins with rainfall to lessen the overly intense sugar concentration, it quickly yields ethanol. Thus it was common tradition that the honey drink or mead predated wine, and *méli* provides the generic word for intoxicated beverage as *methú* and the Demotic Greek verb for 'drunkenness' (*methisménos*). Mead, like wine, however, is similarly limited in the concentration of ethanol that the yeast can produce. The Nordic meads of legendary potency derived their toxicity similarly from fortifying additives (Ruck *et al.*, 2007: 153-155), and it was the common custom throughout the ages always to add other toxins into all forms of fermented beverage (McGovern, 2010).

The bee provides the natural prototype for the female herb gatherer, since it goes from flower to flower, collecting the nectar for the honey (Plato, *Ion*). It also presents a model of a matriarchal sisterhood centering upon its ovulating queen. A gold ring from Minoan Isopata near Cretan Knossos depicts a group of women gathering a magical flower that accesses mystical vision, indicated by the single disembodied eye. They have the faces not of human females, but of an insect, probably intended as bees, which was their title as priestesses. The bee metaphor persisted into Classical times, where various priestesses (of Artemis, Apollo, and Demeter) bore the tittle of Melissa, including the Pythian prophetess at Delphi, where still above the later sanctuary on Parnassus the bacchants swarmed out of the Corycian Wolf Cave like bees (Homeric *Hymn to Hermes*, 550-564).

The honey of these bees was symbolically psychoactive, Inspiring mellifluous inspired speech and interchangeable with the toxins of serpents and magical flowers as the source of mystical experience (Pindar, *Sixth Olympian Ode*; Ruck, 1976). Serpents were thought to derive their venom from eating toxic plants (Virgil, Aeneid, 2.471), and plants acquired their poisons by proximity to serpents (Nicander, *Alexipharmaca*, 521; Pliny, *Natural History*, 9.5), while bees obtained both their honey and their sting from the same obvious common source. Honey from toxic flowers, moreover, can be powerfully psychoactive (Xenophon, *Anabasis*, 4.8.20-21).

The bee is inseparable as a mythical motif from the bear. The animal is notorious for its fondness of honey, and some species even eat the bees. The bear walks upright and appears to be a gigantic human, perhaps enchanted into this ursine transmogrification, an impression seemingly proven by the animal's response to the human pheromone. The motif occurs in the tale of Callisto, a byname of Artemis, who was metamorphosed into the constellation of the Great Bear, and in the name of the goddess's pubescent troupe of girls as 'cubs' (*árktoi*).

In addition to the plants gathered, the bacchants handled serpents (Euripides, *Bacchae*, 698), and are frequently so depicted in vase paintings. Serpents can never be separated from the notion of toxicity, and there is explicit mention of milking them for their venoms in a bacchant context (Demosthenes, *On the Crown*, 18.260). Olympias became a great aficionado of the revels in the various Zerynthian Caves throughout Thrace, and she told her son that she had conceived him from Zeus in the form of a serpent, an event upon which Philip apparently spied, for which he lost the sight of one eye (Plutarch, *Alexander*, 3.1). A similar tale was told about Atia, the mother of Octavian Augustus, who entered an entranced state during a midnight ritual for the god Apollo. It left its mark on her body as a blemish, the same color as the snake, and just before her delivery, her husband dreamed that her womb opened to emit a solar beam that extended to the universe, a dream that she too had independently (Suetonius, Octavius Caesar). Conception through the agency of a serpent implies the whole botanical complex that united serpents, bees, and their shared toxicity with plants. Such tales are typical of the hagiography of famous men, but they indicate the sexual metaphor as descriptive of the orgiastic drug-induced revel as communion with deity.

The bacchants may have suckled fawns and wild wolf cubs (Euripides, *Bacchae*, 699-700), although more probably these events enter into the realm of metaphor, since it is inconceivable that the women, untrained in hunting, could have managed to catch their nurslings and it is unlikely that they brought them with them to the mountain bacchanalia. Since some of the animals seen depicted, such as leopards, are ferocious, the animals are probably zoomorphic materializations of the animate spirit of the gathered plants. Thus the women are seen cavorting with wild bulls, and they were said to have rendered the animals, limb from limb. The bull was hardly likely to submit to such treatment, nor is it believable, except as metaphor, that even groups of women together could accomplish such a feat, which in actuality would require teams of opposing horses. The same is true of Pentheus and Orpheus, both rendered by the bacchants. In the case of Pentheus, his decapitated head was placed atop the thyrsus, like a plant gathered from the mountainside. As a mythic motif, they both represent the materialized personae as surrogates for the deity in his manifestations that predate viticulture, and they thus oppose his new gift of wine. Significantly, Pentheus was plucked from the top of a pine tree, where the god had placed him as the wild surrogate (Euripides, *Bacchae*, 1063-1083).

Just as ivy, bryony, and smilax resemble the cultivated grapevine, but are intoxicating in their natural state, it could be expected that mushrooms figured as additives to the wine, inasmuch as fermentation was recognized as a controlled fungal growth. Mushrooms themselves were called a 'fermentation of the earth' (Nicander, *Alexipharmaca*, 521). In common culinary Latin nomenclature, the stipe of the mushroom was termed its thyrsus (Apicius, 7. 15. 6), making it the natural prototype for the narthex stuffed with the toxins of its cap. Fermentation was also thought to resemble the process of the corporeal putrefaction of the corpse in its moldy interment and thus linked wine as a mediation with the chthonic realm. A similar connotation resulted from the lingering noxious odor of rotting imparted to the vessels for fermentation by fumigation with burning sulfur, as an antioxidant to retard the acidification of the wine. The mushroom's funereal symbolism made it the common shape for numerous tombstones, from all regions and spanning entire antiquity. None of these can rightly be identified as simply phallic. The most explicit is the Hellenistic tombstone of Lysandra from the southern shore of the Black Sea (Kurtz and Boardman, 1971: 242-244).

A *hydria* vase from the cemetery of ancient Thracian Enez (Ainos) depicts the mixing of a *pithos* of sacramental wine under the supervision of a priest (Museum of Edirne; Ruck *et al*., 2014). Along with other plants (vines like bryony and smilax), a mushroom is being offered to a priest for inclusion in the mixture. This is quite probably the famous wine of Maron.

Harvesting Monsters

The most famous of the monstrous anthropomorphisms that materialized from the gathered herbs is the Gorgon Medusa, a version of the goddess Athena, whom the hero Perseus plucked as an apple with a pruning hook. Its identity as a mushroom is documented both as depicted in art (fourth-century BCE *amphora*, Berlin, F. 3022; Wasson *et al*., 1978: image 7) and in the local mythical traditions reported by the second-century CE ethnographic traveler Pausanias (*Description of Greece*, 2.16.3). As further confirmation, Perseus placed the harvested head in a *kíbisis*, an open-topped sack slung on his arm, and so depicted in numerous vase paintings. Such a sack is still used today by pickers of fruits like apples. The Medusa's head was depicted as analogous to a golden apple from the Tree of the Hesperides. The 'apple' was metaphorically psychoactive, since the magical steed Pegasus sprung from the monster's severed neck. The horse is named for the springs of inspiring waters that flow wherever he touches earth, and he functions as the flying vehicle for the harvester, an obvious metaphor for shamanic transcendence accessed via a psychoactive plant.

The Gorgons, among their other zoomorphisms as horse, mermaid, swan, pig, and serpents, mooed like cows (Eustathius, on *Iliad* 2.498; Stephanus of Byzantium, *s.v.* Mukale). The cows in myth are constantly in estrus, like the bovine metamorphosis of the cow-maiden Io, stung by the sting of her herdsman's cow-prod, transmogrified into the cow-fly *Tabanus bovinus*, the Greek *oístros*, which is the etymology for estrus. The mooing is the complement to the bellowing of their taurine mate. It is the sound that mushrooms in Greek make as they burst into fruit from the ground (Aeschylus, frag. 6, probably from his *Perseus* tragedy; Euripides, *Bacchae*, 691). The common designation of the fungus as a 'mushroom' in English is an onomatopoetic bovine zoomorphism as a moo-shroom, derived from the Greek *muá-ein* and Latin *muss-are* for 'mooing or bellowing,' Late Latin *mussarion*, French *mousseron*, assimilated into English as early as the Elizabethan Age. The mushroom stung by the cow-flies immediately suggests the common association of the

Amanita muscaria with flies, as the fly agaric or French *tue-mouches* and German *Fliegenpilz*. It grows in mycorrhizal symbiosis with the host tree, like another of its fruits. The indigenous Anishinaabeg of North America call it the 'tree-mushroom,' *miskwedo* (Keewaydinoquay, 1984).

Seafaring

The deities of the Mystery on Samothrace are commonly cited as the Dioskouroi (Dioscuri), the twin sons of Zeus, male twins of their sisters Helen and Clytemnestra, from his insemination of Leda of Sparta, having taken the shape of a swan. The Winged Victory or Niki of Samothrace now displayed on the landing of the Denon branch of the Louvre in Paris dates from the second century BCE as a dedication from the island of Rhodes commemorating a naval battle. Niki figures were frequent decorative motives designating the Mystery. The Dioskouroi were invoked by imperiled sailors, and the Mystery was supposedly an assurance of safety at sea (Burkert, 1977; Mikalson, 2010) or for profitable commerce from trade at sea (Blakeley, 2008, 2013). Few initiates, however, would be apt to travel frequently at sea.

This interpretation, moreover, ignores the antiquity of the rite at the Zerynthian Caves, both on Samothrace and throughout Thrace, and the ecstatic nature of the original bacchanalia and the copious drinking as later practiced in the lower sanctuary. The metaphor of life's course as a hazardous voyage at sea was a common poetic motif, including the government or piloting of the ship of state.

There was a forge adjacent to the sanctuary, considered not relevant by the excavators, but implying the theme of spiritual transcendence in the volcanic caldera, analogous to the ennobling of ores through metallurgical alchemy. Many rings of ferromagnetic iron were cast as souvenirs of the initiation (Cardew, 2012). They symbolized the broken link from the chains that bound them formerly to the delusional imprisonment in the cave of ordinary vision. It is significant that the chain dance was an element of the ritual. Similarly, iron magnets and the electrostatic attractive force of amber were sacred to the religion. Amber in mythic tradition represented the gummy tears of the Daughters of the Sun metamorphosed into poplars, encapsulating the sun's brilliance, and it was commonly thought that all mushrooms were derived from such resinous exudations of trees (Pliny, *Natural History*, 22.96.1). Amber had particular significance as a homeopathic remedy for madness, and the resinous pitch was also seen as the menses of the tree and efficacious as an aphrodisiac. Thus, both the magnet and amber are emblematic of eroticism.

The devotion of the Dioskouroi to each other was so great that although only one of them was immortal, and the other mortal, they vowed to share immortality together on alternating days. They thus were constantly engaged in the metaphoric voyage at sea across the great aquifer of Ocean that separates the living from the dead. They materialized as the electrostatic discharge that flashes like lightning from the masts of ships, known as St. Elmo's fire, still called *dioskouroi* in Greek. They were assimilated into Christian hagiography in the account of St. Paul's shipwrecked voyage on the Alexandrian boat called Dioskouroi, where Christ usurped the role of savior for ships at sea (*Acts of the Apostles*, 28.11).

Wolf Mushroom

The Dioskouroi were imagined as handsome youths, wearing the birth remnants of the halved eggshell as Phrygian caps upon their heads, but there were less iconic versions of their portrayal as twin shields or just a pair of fox-caps or linked twin pillars in landlocked Sparta, where they symbolized not foreigner travel, but the shrine of the opened tomb awaiting offerings. As the twin pillars, they were also carried into battle by the Spartan troops, who were identified as packs of wolves. They are personifications of the mushroom of the initiatory wine of Samothrace.

The lycanthropy and the related motif of rabidity as metaphoric for the altered state of consciousness of the bacchants derives from the association of the wolf with the *Amanita muscaria*, upon which it feeds. In the New World, it is documented among the Huichol as the occult initiatory sacrament of their elite wolf warriors (Hoffman, 2001), and among the Ahnishinaabeg for its access to heightened physical endurance and strength (Keewaydinoquay, 1984), as also claimed by the bacchants. It was the sacred intoxicant of Thracian warriors, traceable back to the mid second millennium BCE, and documented as lycanthropy in the Homeric episode of the Thracian horseman, Rhesus (Homer, *Iliad*, 10; Ruck *et al*., 2007: 87-124). It was still documented as a mushroom cult at the time of the Emperor Trajan (Dio Cassius, *Roman History*, epitome 68.8.1) among the Thracian Dacians, named as the 'Wolf-people.' They bore the emblem of Draco, their wolf-headed serpent, into battle. It is the same initiatory mushroom cult associated with the Nordic berserkers, named as the 'bear-shirts,' who materialized on the battlefield either as werewolves or in ursine transmogrifications. In folkloric tradition, it survives in the tale of *Rotkäppschen*, 'Little Red-cap,' named for her Phrygian mushroom cap, and the episode of initiatory lycanthropy (Ruck *et al*., 2007).

It is the ancient sacrament of the Zoroastrian Persians, *haoma*, the Avestan analogue of the Vedic Soma, known to the Greeks as *[h]ómomi*, assimilated as the Homeric *mólu* (moly), and associated with wolves (Plutarch, *Isis and Osiris*, 46). An elite troupe of Scythian warriors in the sixth-century BCE Achaemenid army were named as the *Saka Hauma-varga* or 'Haoma Wolves.' A recently restored fabric from the burial cloth of a Mongolian woman, dating to the second century CE, depicts a Zoroastrian priest presenting the deceased a large mushroom, identified by the Russian restorers as a psilocybin *Stropharia*, but probably too large and more likely an *Amanita*, discolored by the age of the tapestry (*Science*, vol. 26, no.2).

Eagle Fare

As the Gemini, the form the Dioskouroi assumed when they ascended to the realm of the constellations, they encode an ancient riddle about the herb that sprouted from the ichor or divine fluid that fell from the liver of the Titan Prometheus, the creator of man, as it was gnawed upon by the eagle of his torment, as eternal punishment for having stolen fire from the gods. The liver was considered a microcosmic image of the cosmos and, therefore, the seat of divination. The liver also acts as a filter for toxins and thus contains the highest concentration of ingested psychoactive plants. Since the Titan placed the fire he stole in a thyrsus, the event was analogous to the gathering of a sacred plant.

The riddle about this Promethean herb, which was picked by Medea, a priestess of Hecate, was that it was like the flower in the Wolf Cave at Delphi and that it sprouted from the earth with a 'twin' stem. (Apollonius Rhodius, *Argonautica*, 3.838 *et seq*.) It gave Jason the meaning of his name as the 'Drug-man' and let him access the strength to plow the field with the fire-breathing bulls and plant the toxic seeds of serpent fangs. This is not a branching stem, not even a double stem, but a twin (*dídymos*, *geminus*), characteristic of no plant but the *Amanitas*. As it expands from the egg shape, splitting its cap into halved eggshells, the single stipe extends in both directions producing the defining dumbbell of the birthing mushroom. The divine thunderbolt of Zeus was customarily depicted in Greek art as such a dumbbell, a bi-conical object, often with conventional lightning flashes attached. It is the same shape as the Vajra thunderbolt of Vedic Indra, and in Buddhism it is symbolic of the thunderbolt experience of enlightenment. As the Gemini, the Dioskouroi were depicted in medieval lore as Siamese twins, a form attested in antiquity for their Spartan doublets, the Moliones (Plutarch, *On Brotherly Love*, 1). They are the original of the primordial spherical creatures who were split in two to make the race of human, eternally seeking its erotic complement in reuniting with the beloved other half (Plato, *Symposium*, 186c *et seq*.; Ruck *et al*., 2001: 124-125).

The sources that identify the deities of the Mystery as the Dioskouroi make clear that this is not the true identity of the divine twins who were transported to the stars, which must never be told, but that they encode a symbolic manifestation of the regenerative spirit of primal man, not actually brothers, but twin siblings, a couple, male and female (Varro, *On the Latin Language*, 5.10.57-58). This also suits the hermaphroditic persona that the mushroom displays as the phallic thrust of the extending stipe appears to penetrate the vulva of the inverting cap. In Corinth, the tradition was preserved that Sisyphus, by some accounts the father of Odysseus, created the first indigenous people out of mushrooms after a rainfall (Ovid, *Metamorphoses*, 7.392-393).

The *Amanita muscaria* is commonly called 'raven's bread' because of the bird's fondness for ingesting the mushroom (Klapp, 2013). 'Bread' was an obvious metaphor for mushrooms, similarly spongy and leavened, the likeness of the heaven, just like the prophetic liver of haruspicy. It is unlikely that the raven alone eats the mushroom, and other birds are probably interchangeable in its designation. Its association with the thunderbird is attested in Ahnishinaabeg folklore (Wasson, 2001). The prophet Elijah was miraculously fed in the desert by a raven that brought him meat and bread (*I Kings*, 17.6), and it is the Raven who serves the cosmic bread and drink of the so-called bull's blood at the divine banquet to the Pater in Mithraism. In Classical tradition, the quail, which was known to eat things that were toxic to men, rendering feasting upon the quail potentially lethal (Aristotle, *History of Plants*, 820.6-7; etc.), is an analogue of the eagle's fare. The quail's erratic behavior made it appear drunken with epileptic seizures of the sacred disease, called 'quail madness' (*ortugomanía*). It is probably this bestiary lore that made the bird sacred to Apollo and Artemis. Their mother had a comic epithet as 'Mother of Quails' (*ortugométra*, Aristophanes, *Birds*, 870). The pubescent priestesses of Artemis danced a drunken staggering in imitation of the quails. Second only to the identification of the Gorgon Medusa as a fungal anthropomorphism, there could be no motif more central to the ethnobotany of ancient Greece than this divinatory liver of Prometheus.

Dirty Dancing

The Dioskouroi in the Mystery of Samothrace were interchangeable with the Corybants, who sprung from the fingers of Rhea as she groveled in the earth, bent in labor for the birth of Zeus. The posture suggests that they, too, belongs to the motif of gathering sacred plants. They are named as the 'helmeted dancers,' who protected the infant, hiding his birth cries by drumming on their shields. They were interchangeable with the Kouretes, who are named simply as the boys. Like the Dioskouroi, these all are visualized as idealized young men. Their typical dancing stance is raised on a single foot, with the shield held implausibly over their heads, a stance that Attis and Mithras also assume in some versions of them as warriors.

In the folklore of fantastic creatures, they appear revealed as fungal anthropomorphisms with the name of the Kaulomycetes or 'Cover-mushroom' warriors (Lucian, *True History*, 1.16). These were warriors who held their mushroom cap as a shield over their heads and fought with an asparagus for a sword. With these details, we enter a realm where the Mystery creatures are apparently less than normal size, small enough for the mushroom's cap to serve as shield for a warrior imagined beneath it, who fights with an asparagus stalk. The choice of botanical sword is disproportionally long for beings so tiny and suspiciously phallic, and the asparagus was reputed to have aphrodisiac properties and it is slang for the penis. Hence the erotic implications of the Corybants as initiators of Cleinias, the younger brother of Alcibiades, into the Samothracian Mystery in Plato's *Euthydemus* dialogue (Levenson, 1999). The single foot stance of the Corybants and Kouretes defines another fantastical fungal anthropomorphism. These are the Skiapodes ('Shade-foots'), a tribe of creatures with only a single broad foot, upon which they vigorously dance, until they tire and fall upon their backs to rest in the shade of their one foot spread above like a parasol or (Ruck, 1986: 151-178). The parasol (*skiádeion*) is an obvious metaphor for the mushroom and these creatures survived in medieval art and are recognized as fungal in European folklore (Lewis, 1952). Aristophanes presented Prometheus as such a Shadefoot in the *Birds* (1494 *et seq.*), hiding from the celestial gods above beneath his *skiádeion*, which, when unfurled, turns out to be the comic disguise for his gigantic phallic erection (Ruck, 1986). The 'mushroom' was a common metaphor for an erect penis (Henderson, 1975).

The Great Gods of Samothrace, at least in their herbal personae, belonged to the cult of the little people, common in the Celtic lore of Europe. Interchangeable with the Dioskouroi, Corybants, and Kouretes were the 'finger' creatures or Daktyls. They, too, sprang from the fingers of Rhea as she picked the sacred plant for the birthing of her divine son, Zeus. Although their dactylic personae suggest their erect penises, they also had an equal handful of sisters, and hence the groups of little creatures could appropriately engage in sexual revels.

Among such dwarfish beings of the Mystery were the Kabeiroi, gnomes, imagined as ithyphallic African grotesqueries and their female companions, similarly oversexed. Dwarfism is the converse of gigantism, as in the tiny brothers of the African giant Antaeus, the reference for Jonathan Swift's tribe of Lilliputians (1726), and the alteration in size is metaphoric of the penile erection, and also suggests the alternating macroscopic and microscopic vision characteristic of the *Amanita muscaria*, as popularized in Lewis Carrol's *Alice's Adventures in Wonderland* (1865). The name of the Kabeiroi is plausibly linked etymologically with Cybele. In ancient Greek folklore, they are known as *kóbaloi*, trickster, thieving goblins (Aristophanes, *Knights*, 450; *Frogs*, 1015; *Plutus*, 279, etc.). They are shape-shifters (*ailomórphoi*), attendants upon Dionysus, dancing maniacs (*choroimanéis*) (Brown, 2004: 230-231). Two of them who are twins are named as the dwarfish Kerkopes ('Tail-faces'), depicted with African or simian features, whose monkey 'tail' presents them backwardly phallic. They survive in the folklore of Europe as the German *Kobald*, the French *gobelin*, and the puck of England (Hardwick, 2007).

Odysseus, Circe, as Kabeiroi, and the potion are frequent motifs on the drinking vessels from the Mystery sanctuary outside Thebes. Circe, although not otherwise known for her weaving in the Homeric tradition (Homer, *Iliad*, 302-347), is shown interrupting her work at the loom to offer the ithyphallic Odysseus the potion that turns men into pigs. The comb (*ktéis*) was the equivalent of the phallus. It held the threads of the loom's warp threads apart for the penetration of the cock, back and forth, with the threads of the weft. Terracotta models of the 'comb' in antiquity were almost as abundant as phalloi. The depictions of the Kabeiric Circe are thus as obscene as the gnomish Odysseus. Aristophanes staged an obscene choral dance in his *Plutus* comedy (408 BCE, revised *ca*. 388), where the asshole of a Corinthian hetaera named for the famous enchantress serves as the mortar for mixing the Mystery potion (290-315). Circe notoriously turned men into pigs. Boars, like the bear, respond to the human pheromone, and piglet was slang for the female's comb or pudendum (Henderson, 1975). The phallic thrust of the mushroom's stipe can be imagined as penetrating through the webbing threads of the radiating gills on the underside of the cap.

When not depicted as such misshapen gnomes, the Kabeiroi were crabs (*kárkinoi*), sons of Hephaestus, attending him as henchmen at the alchemical forge of transmutation. Hephaestus himself at the forge was imagined as wearing the red eggshell cap (Phrygian *pileus*) symbolizing the vault of heaven, a common metaphor for the pileus of the *Amanita*, suggesting transcendent experience. The emblematic tool of metallurgy was the god's pincers, which were called 'crabs.' Aeschylus staged them as tiny pubic lice dancing around a giant erection in his *Wasps* comedy (422 BCE), punning upon the snot ejaculating from the bellowing erection (*muktér mukátai*). The mushroom is named in Greek *mykes* for its slimy mucus, as typical, not a name, but an epithet, for something too sacred and taboo to have a proper name. The scene is the culmination of a parody upon the Samothracian Mystery and the visionary phallic mushroom of the Persian *haoma*-wolves (Ruck, 2012).

The Lemnian forge, where Hephaestus copulated with his wife Aphrodite, was the source of the fearsome sexual stench of the Lemnian women, and Aristophanes staged the odiferous combat of opposing pheromones as the divided chorus of grotesque male and female Kabeiric dancers in his *Lysistrata* comedy (411 BCE) (Ruck, 2016: 160-208). The metallurgical forge is traditionally seen as a womb tended by specially initiated males, with its slag as its menses (Blakeley, 2006).

Crazy as a Loon

The Kabeiroi as crabs walked sideways, like the smithy god Hephaestus, whom they served. The god himself had backwards feet (*amphiguéeis*) and an ambidextrous manner of walking, characteristic of drunkenness. Hermes, who was patron of the Samothracian Mystery, famously turned the feet of the cows mooing in estrus backwards (an impossible feat for cows, named as *próbata* or 'forward-walkers') and he wore his sandals turned around for the event, as narrated in the Homeric hymn, probably intended for recital in the Samothrace sanctuary. Aristophanes, who was obviously an initiate into the Mystery on Samothrace, introduced Hermes in this role of backwards ambulation in his *Peace* comedy (421 BCE), which staged the flight of the hero in the persona of Perseus flying to heaven on the gigantic mushroom of his erection portrayed as a dung beetle in the persona of Pegasus (Ruck, 2016: 94-115). Aeschylus, who also was an initiate of the Mystery of Samothrace, staged the initiation of the Argonauts as a drunken revel of the sailors with the Kabeiroi (Aeschylus, frag. 48, 49).

Ambidextrous ambulation is a version of shape-shifting. Thus another version of the god's attendants at the volcanic forge were the wizards called Telchines or 'Enchanters.' They had the ability to shift shape and become seals. Like the crab, the seal is characterized with a handicapped mode of ambulation, inasmuch as its hind limbs are bound together, causing it to slither its way forward, rocking back and forth, appearing drunk and leaving a zigzag trail like a serpent. Their drunkenness was interpreted as lycanthropic rabidity, since that were said to have metamorphosed from the rabid hounds of Actaeon. They are comparable to the selkies of Celtic lore, who assume human form on land and are notorious for their sexual proficiency. Shapeshifting and ambidextrous ambulation were emblematic of divination. Thus the grandfather of the Kabeiric males and females was cited as Proteus, the seal-keeper and famous prophet. Seals are noted for their fishy stench, which implies the sexual pheromones. The same ambidextrous orientation characterizes the Kerkopes, with their 'tails' on the wrong side, and also the paired brothers, Prometheus, with his backwards minded sibling Epimetheus. Additionally, the backward-tailed Kerkopes were usually depicted upside-down, from which vantage their forward vision was reversed backwards.

One of the foundational myths for the Samothracian Mystery describes Dardanus sailing on a goatskin raft, drunken and crazy as a loon (Lycophron, *Alexandra*, 69-82), whose eerie screams and erratic diving suggest spiritual possession and the same motif of drunkenness, hence the comparison 'crazy as a loon.' Virgil connected this obscure tradition of the fungal drunkenness of Dardanus with the Trojan ancestry of Aeneas in the foundational myth for Rome. The city would not be founded until Aeneas and his men were forced to eat their own tables (*Aeneid*, 3.254-257). The site would be indicated by tables laden with the slimy mucous offal of the Harpies, the repulsive food that had given the prophet Phineus the awesome power of prophecy. The Harpies materialized as elfin eddies (Homer, *Odyssey*, 20.66, 77), like the Celtic fairies, and also as swarms of flies (Apuleius, *Golden Ass*, 10.15), suggestive of the particular species of mushroom. These tables are a version of the *Amanita muscaria* mushroom, spread with the scabby white remnants of its shattered veil like bits of bread attracting swarms of cow flies, tables that belonged to the fairies and of which it was forbidden to eat (Ruck and Larner, 2013). The fairy lore of northern Europe occurs in ancient Greece, as well. The figure of Psyche is commonly depicted with butterfly wings, as on the mushroom tombstone of Lysandra, and even the Gorgon Medusa, as might be expected, can be portrayed with fairy wings (Athenian black figure *lekythos*, ca. 450 BCE, Metropolitan Museum, New York). The 'Great Gods' of Samothrace was a cult of the 'little people' (Ruck, 2016).

A bizarre analogue of this foundational myth involves the Kabeiric Odysseus and Circe (Lycophron, *Alexandra*, 1226 *et seq.*) One of the Kabeiric drinking vessels depicts Odysseus, nude, dwarfish, with African features and grossly ithyphallic with sagging belly, sailing like Dardanus on a raft of two amphorae, probably depicting the export trade of Maronian wine from Samothrace (late fifth-century BCE *skyphos*, Ashmolean Museum, Oxford, inv. no. V.262). The other side of the cup depicts the Kabeiric Odysseus, with erection, confronting Circe and her comb, as she presents him with the potion. Another obscure account of this raft of the drunken loon mentions four legs in a basket, referring to the two dancers treading the grapes of the vintage in the straining basket.

Although the Roman Penates were imagined, like the Dioskouroi, as idealized adolescent males, they were traditionally represented as figurines, which is to say, of diminutive size. The original Penates that Aeneas brought from Rome were preserved in a temple on the Tiber south of Rome, and although probably pious forgeries in Classical times, they replaced creatures like the ithyphallic grotesqueries of the Mystery. Like the twin yoked pillars of the Spartan Dioskouroi, the Penates were guardians of the innermost recesses of the household, the *penetralia*, which implies the motif of sexual penetration, and in antiquity interpreted as penetration into the secrets of mystical vision. At each meal, an offering was made to the Penates to remove the accursed taint of primordial toxicity and render the food safe for consumption.

The Etruscan version of these little creatures is their Tages, a little young old man, who popped up in the plowman's path and dictated the book of secrets and taught the art of divination by inspection of the liver. The name of the plowman is a version of Tages, and also the origin of the tribal designation of the people.

Demeter's Indiscretion in the Cornfield

The fungal identity of all these Samothracian grotesqueries is expectable since another foundational myth for the Mystery of Samothrace involves, not the drunken sailing of Dardanus, but the inaugural plowing for the foundation of the Greek city of Thebes and a parallel of the Eleusinian adduction of Persephone. By this account, at the marriage feast of Cadmus and Harmonia, Demeter had sex with Iasion (or Iasos/Iasios, a brother of Dardanus) in a cornfield. This Iasion was an ithyphallic Kabeiros creature. In this telling of the tale, Harmonia was also probably a Kabeiros, since she is the sister of Iasion and Dardanus. The latter two were cited as the original Kabeiroi (Apollonius Rhodius, *Argonautica*, 1.917, scholia), and one killed the other. Iasion is named as the 'Drug-man' and is a doublet of Jason anointed with the chrism of eagle-fare.

Demeter taught Iasion how to plow. He was named Triptolemos for the first 'three furrows' (*trípolos*) cut into the primordial cropland, symbolic of the vulva, tripartite for the triple goddess, repeated annually as an inaugural ritual in a plot dedicated in his honor. The plow was his phallic stick, and so recognized in the legal terminology of the marriage contract for the plowing of legitimate children. For this affront to

Demeter/Persephone's virginal modesty, the primordial plowman was sacrificed, repeated thereafter with an offering of a victim at the annual inaugural plowing. The symbolic offering of victims in the persona of the primordial plowman represented an accommodation with the forces of primitivism, which yielded to the evolutionary arts of agriculture. He plays the same role as the primordial antecedents to viticulture, and botanically he was manifest in the single or dual kernels of the most primitive edible grass, which was spelt ('split-dual kernel') or German *Einkorn* ('one-kernel'), known as 'goat grass' in Greek. This primitive grass resembles the ergot that grows on the cultivated superior grassy hybrids like barley. Ergot is so named for the 'cockspur' in French, which in antiquity would be the 'talons' of ornithological creatures like the Harpies. The ergot was recognized in antiquity as a fungus since the sclerotia of infested kernels of grain fruit as mushrooms visible to the unaided eye. It was the psychoactive ingredient of the Eleusinian Mystery potion, representing the seed of the totally wild and seedless mushroom, and thus the mediation between the wilderness of the mushroom's habitat and the cultivated cropland. The ergot in an aqueous context with bone ash, representing the sacrificed plowman, yields an oscillating hydration of ergine and isoergine, LSA, which is a natural analogue of LSD.

Triptolemos and Demeter proselytized the art of agriculture throughout the world. It was a flight in a special cart, through the air, metaphoric for ecstatic transcendence. It was the very same cart drawn by toxic serpents in which Jason's Medea flew. Her name is merely the adjectival version of the participial form it has in the Gorgon Medusa as the 'Queen.' Medea inherited this very same solar cart from her aunt, Circe, the Kabeiric lover of the grotesque ithyphallic version of the dwarfish Odysseus.

Analogous to the controlled fungal growth in the yeasts of vinous fermentation, was Demeter's gift of bread. Leavened bread is similarly a fungal growth, yielding the spongy dry food, the civilized analogue of the sponge that provided the metaphor for the mushroom as a fungus (*spóngos*), and for the metaphor for the bread of ravens and thunderbirds. The sponge belongs to the tradition of the fungal Medusa, since the blood from her harvested head metamorphosed into coral, which becomes hard and petrified only when immersed in water, and the spongey expansion of the mushroom's fruiting was metaphoric for the heaving upwards of the cosmic rim of the heavens. Thus both wine and bread as the fundamental liquid and dry foods of antiquity partake of the same evolution of primordial toxicity into the arts of civilized cultivation.

Epilogue

I. What was s&umacr;kara-maddava?

Upwards of a dozen scholars[1] in the past century have commented on what the Buddha ate at his Last Meal, *ca*. B.C. 483, and the puzzling mystifications in the evidence. The meal was served to him and his suite of monks by his host the metal-worker Cunda at P&amacr;v&amacr;, a village that lay near Kusin&amacr;r&amacr; where the Mah&amacr;parinirv&amacr;ṇa - the 'Great Decease' as the Rhys Davids translated it - was scheduled to take place some hours later. The canonical P&amacr;li Text says that Cunda served his august guest *s&umacr;kara-maddava*, a hapax in P&amacr;li. Walpola R&amacr;hula, the Buddhist monk and scholar residing in the West, has assembled in a memorandum for us the relevant P&amacr;li texts with his translations and notes, and this document is appended to our paper.

The first part of that compound word, *s&umacr;kara-*, is simple: 'pertaining to swine,' *s&umacr;k-* being cognate with Latin *sus*. The second element is generally thought to mean tidbits, dainties, but whether as a specially delicate part of the pig's meat or as a food of which swine were specially fond, whether a subjective or objective genitive, no one can say. Rhys Davids noticing that in Bihar there was a common edible underground fungus, translated *s&umacr;kara-maddava* by 'truffles.'[2] This was a successful pitch, considering that by 'truffles' he meant an underground fungus common thereabouts, although no truffle (= *Tuber*) has been discovered so far in Bihar. His underground fungus was a *Scleroderma*, a little snow-white ball that is gathered just as soon as it appears on the surface. There are a number of genera of underground fungi of which truffles are one, and each genus has many species.

The two canonical P&amacr;li Commentaries discuss but do not agree on the meaning to give to *s&umacr;kara-maddava*. One of them is the canonical P&amacr;li Commentary on the *D&imacr;gha Nik&amacr;ya*, *Sumaṅgalavil&amacr;sini*, and the other, the *Paramatthajotik&amacr;*, the canonical Commentary on the *Ud&amacr;na*. These Commentaries took their present form in P&amacr;li under the guidance of the celebrated monk Buddhaghoṣa early in the fifth century of our era, mostly from Sinhala sources available to him. Each of these commentaries suggests various dishes as possibilities. Both include pork and an 'elixir' (a chemical preparation) in the list of choices. The canonical P&amacr;li Commentary on the *D&imacr;gha Nik&amacr;ya* adds soft rice with the broth of the five products of the cow. The canonical P&amacr;li Commentary on the *Ud&amacr;na*, deriving its authority from the Great Commentary (now lost) that dates from the third century B.C., offers two further choices: bamboo shoots (sprouts) trodden by pigs, and *mushrooms grown on a spot trodden by pigs*.

That the Buddha was eating his last meal was known to everyone thereabouts: nothing that happened there could have escaped those within eye-reach nor have been forgotten by them, not least because of the awesome event to take place a few hours later, the Buddha's translation to Nirvana that he had been predicting for that night since he was in Vai&sacute;ali three months before.

Dr. Stella Kramrisch, building on the work of the late Professor Roger Heim and me in eastern India, has identified with finality the *s&umacr;kara-maddava* as the *P&umacr;tika*,[3] a plant that figures conspicuously in the Br&amacr;hmaṇas and other early post-Vedic sacred Sanskrit texts. In this paper I will examine the Last Meal at P&amacr;v&amacr; and the death of Gautama the Buddha at Kusin&amacr;r&amacr; in what is today northern Bihar. I will focus attention on what he ate at his Last Meal - a matter of little theological importance to the Theravadin branch of Buddhism and none at all to the Buddhists of the Greater Vehicle, but pertinent to our mushroomic inquiries and notably, as I shall show, to the identity of Soma.

Of all the scholars who have dealt with the Last Meal of the Buddha, I believe only one, André Bareau, has addressed himself to the surprising anomaly offered by the possibility of either pork or mushrooms being served to the Buddha at this meal. Here is what Bareau has to say:

> En effet, la viande de porc et plus encore les champignons sont des choses pour lesquelles les Indiens impregnés de culture brahmanique, comme l'étaient le Buddha et une grande partie de ses disciples, éprouvent un profond, un insurmontable dégout et que ne consomment guère que certains tribus sauvages ou des gens de basse caste, rejetés par la bonne société et pressés par la faim. L'idée d'offrir au Bienheureux, pour l'honorer et le régaler, comme un mets de choix, ... de la viande de porc ou des champignons est aussi insolite que si, dans une légende occidentale, on offrait à quelque éminent personnage un festin dont le plat principal serait une cuisse de chien ou une purée de goémon, des sauterelles frites ou des chenilles grillées; cela paraîtrait à juste titre une plaisanterie ou ferait croire à une erreur de copie. [*Recherches sur la biographie du Buddha*. Tome 1, p 267. Paris. 1970. Publications de l'Ecole Française d'Extrême-Orient, Vol LXXVII]

Confirming what Bareau says, Chap V-5 of the laws of Manu, believed to have been committed to writing around the beginning of the Christian era, declares that:

> garlic, leeks and onions, mushrooms and (all plants) springing from impure (substances), are unfit to be eaten by twice-born men,

and this proscription is repeated in V-19:

> A twice-born man who knowingly eats mushrooms, a village-pig, garlic, a village-cock, onions, or leeks, will become an outcast.

Here the prohibition carries a dire penalty. Mushrooms are forbidden in two further clauses, VI-14 and XI-156. The repeated prohibition applies expressly to twice-born men, which embraced the three upper castes.

The ban on mushrooms was no dead letter. Sir William Jones quotes from a commentator on the laws of Manu named Yama:

> ... the ancient Hindus held the fungus in such detestation that Yama... declares 'those who eat mushrooms, whether springing from the ground or growing on a tree, fully equal in guilt to the slayers of Bráhmens, and the most despicable of all deadly sinners.' [*The Works of Sir William Jones*, Vol V, pp 160-161, London, 1807.]

This is the most extravagant outburst of mycophobia that we have found anywhere, surely the most extravagant to be found in the Indo-European world, which is saying a good deal. The learned Brahman tells us that the simple mushroom-eater is as bad as the murderers of Brahmans! Why such passionate, such exaggerated censure? Bareau, in comparing the Hindu eater of mushrooms to one among us who eats dog's flesh, was engaging in understatement.

Three months before the Last Meal at P&amacr;v&amacr; and before his Mah&amacr;parinirv&amacr;ṇa, the Buddha had been sojourning at Vai&sacute;ali and thereabouts. While in the vicinity of Vai&sacute;ali he had suffered a grave illness, attributed from ancient times to a chronic gastric upset, probably dysentery; had felt the weight of his years, had called himself an 'octogenarian,' and had announced his intention to go to Kusin&amacr;r&amacr; and there three months later to experience the Mah&amacr;parinirv&amacr;ṇa, the Final Extinction. He was predicting the time and place of his own end. He made his way to Kusin&amacr;r&amacr; with his followers on foot, teaching the doctrine as was his wont, and it took him three months to cover the 140 kilometers. To his disciples and the villagers he made freely known his purpose: he never wavered in his resolution, nor did he hide it from anyone.

The day before the Buddha reached Kusin&amacr;r&amacr; he arrived at the nearby village of P&amacr;v&amacr; and passed the night in the mango grove belonging to one Cunda, a metal-worker or blacksmith, and therefore a &sacute;&umacr;dra, the lowest of the four castes in Hindu society. Cunda, appearing almost immediately, inquired what the Buddha desired. According to one of the Chinese recensions of the Buddha's life, the Buddha explained that he was to undergo the Mah&amacr;parinirv&amacr;ṇa in Kusin&amacr;r&amacr;: lamentations followed. Cunda invited the Buddha and his many followers to take their single meal the next day with him, and by his silence the Buddha accepted. Cunda withdrew to assemble the food and prepare it. In the morning Cunda came to summon the Buddha and his followers to the meal that he had prepared.

Cunda, as we said before, was a &sacute;&umacr;dra, a man of the lowest caste. On the other hand, as the metal-worker of the region he was a technician, comfortably off, extending hospitality on a moment's notice to the Buddha and his numerous followers, one accustomed to meeting and mixing with travelers including individuals of what are today called the 'scheduled castes,' aboriginal tribesmen who were not Hindus and therefore not a part of the dominant Hindu society. His forge may well have been the *raison d'être* for P&amacr;v&amacr;. When the Buddha arrived at Cunda's dwelling-place and was seated in the place prepared for him, he (according to the *D&imacr;gha Nik&amacr;ya*) addressed Cunda saying,

> As to the *s&umacr;kara-maddava* you have made ready, serve me with them, Cunda, and as to the other food, sweet rice and cakes, serve the monks with them. [Chap. IV, §18, p. 138]

The Buddha then said to Cunda,

> Whatever *s&umacr;kara-maddava* are left over to thee, those bury in a hole. [§19]

In a hole, not just throw away, and we are told that the surplus *s&umacr;kara-maddava* Cunda buried in a hole. Apparently Cunda had brought *s&umacr;kara-maddava* for the whole company, as he had thought all would share in them, so there must have been an ample surplus.

Then the Buddha added these remarkable words,

> I see no one, Cunda, on earth nor in Mara's heaven, nor in Brahma's heaven, no one among the Samaṇas and Br&amacr;hmaṇas, among gods, and men, by whom, when he has eaten it, that food can be properly assimilated, save by a *Tath&amacr;gata*. [§19]

Obviously the Buddha had recognized at once what he was being offered, the *s&umacr;kara-maddava*, and he knew the mushrooms were of a species that would shortly smell bad ('stink') if they were not eaten or buried in a hole. (To this day the custom among some Santal seems to survive to bury any surplus *s&umacr;kara-maddava* in a hole.) Perhaps it was the first time in his life that the Buddha, of kṣatriya origin, was being offered mushrooms to eat. But these particular mushrooms were familiar to him because of their unique role in the Hindu religion in which he had been brought up.

André Bareau appreciates to the full the solemnity of this dish of *s&umacr;kara-maddava*, though he did not know what it was. He says:

> ... cette nourriture, la dernière que consomme le Bienheureux avant son Parinirv&amacr;ṇa, est une nourriture en quelque sorte sacrée, dont les riches qualités, la puissance essentielle, vont lui permettre d'accomplir cet exploit surhumain, la suprême Extinction. Cette richesse, cette

> puissance sont trop grandes pour être supportées par les autres êtres, hommes ou dieux, qui n'auront jamais, et de loin, à exécuter une action comparable. [*Recherches sur la biographie du Buddha*. Tome 1, p. 271. Paris. 1970. Publications de l'Ecole Française d'Extrême-Orient, Vol LXXVII]

Here was the Buddha, at one of the two supreme moments of his life, unexpectedly offered at his last meal a dish that Hindus of the upper castes were forbidden to eat, an edible mushroom, a dish that was the surrogate for Soma when formally sacrificed in an utterly different manner and setting.[3] Buddhaghoṣa quotes the Great Commentary (*Mah&amacr;-aṭṭhakath&amacr;*) as saying of Cunda's motives in offering this dish to the Buddha and his monks:

> They say that Cunda, the smith, having heard that the Exalted One would attain *parinibb&amacr;na* that day, thought it would be good if he could live longer after eating this dish, and offered it wishing for the Master's longevity. [p. 27 *infra*]

Walpola R&amacr;hula's comment on the Great Commentary from which we have extracted this quotation is as follows:

> The *Mah&amacr;-aṭṭhakath&amacr;* (Great Commentary) is the most important of the ancient original Sinhala commentaries dating back at least to the 3rd century B.C., on which are based the present available P&amacr;li commentaries of the 5th century A.C., including the Commentaries on the *D&imacr;gha Nik&amacr;ya* and the *Ud&amacr;na* from which these two commentarial passages are taken. [p. 27 *infra*]

The Great Commentary cites hearsay ('They say...') as the reason that Cunda served those particular mushrooms on that day. The hearsay may be right, but if indeed Cunda felt the dish of *P&umacr;tika* would extend the life of the Buddha, he must have confused the properties of *Soma* and of the *P&umacr;tika*. The *P&umacr;tika* enjoyed a unique status as the exalted surrogate for *Soma*, but, whereas *Soma* was consumed, the *P&umacr;tika*, as Kramrisch quotes the sources,[3] were mixed with the clay and then fired ritually in the making of the Mah&amacr;v&imacr;ra pot and there is no reason to think that the Hindus of the three upper castes or even the Brahman hierarchs ate these fungi. Does not the text of the Great Commentary permit another interpretation: Cunda, a &sacute;&umacr;dra accustomed to eating the *P&umacr;tika*, served them because it was the season of the rains (which had started when the Buddha and his suite were in Vai&sacute;ali) and the mushrooms, which he had known all his life, were fresh from picking? If so, it was the Buddha who at once recognized them because of their role in the Hindu religion and stopped Cunda from serving them to the others. The Buddha was certainly not accustomed to eating mushrooms of an kind, and here he was being invited to eat those slimy mucoid excrescences, as the twice-born Hindus with loathing would view them. May not this, combined with the emotional tension of his imminent extinction, have provoked a recrudescence of his intermittent attacks of dysentery?

I now interrupt our account of the Buddha's progress on his last day to set forth certain discoveries bearing on *s&umacr;kara-maddava*.

II. The Santal and the *Putka*

By an accident of fortune the Santal people living now in western Bihar and Orissa have preserved for us, as though in a time capsule, the identity of the Sanskrit *P&umacr;tika*, a plant until recently unidentified, an ingredient in the clay of the Mah&amacr;v&imacr;ra vessel that was fired in the course of the Pravargya sacrifice. The *P&umacr;tika* is known as having been the surrogate for Soma,[4] though probably today by no Santal, and it figures conspicuously in the Br&amacr;hmaṇas and other early sacred Sanskrit texts. As I said before, it was identified by Kramrisch on the strength of evidence produced by Heim and me.[5] (Roger Heim, outstanding French mycologist, had served as President of the Académie des Sciences and was Director of the Muséum National d'Histoire Naturelle: he accompanied me on many of my field trips.)

The late Georg Morgenstierne, the Norwegian linguist, specialist in the Kafir and Dardic languages, also a

Sanskrit and Persian scholar, first called my attention to an oddity of the Santal language of special interest to me, as it affected their mushroom vocabulary. Santali was not a specialty of his but he was a vast reservoir of general linguistic knowledge.

The Santal, who number some millions, live in villages scattered in the area of eastern Bihar known as the Santal Parganas, in the western north-and-south strip of West Bengal, and in Orissa as far south as the Simlipal Hills. The Santal are slight in build, neat in dress, with sleek, black hair and dark almost black regular features, their houses of red earth ornamented with curious painted geometric patterns and neatly disposed within and without, in these respects contrasting with the Hindus. By tradition they are food gatherers, hunters, fishermen, but are now taking to agriculture.

From the Indo-European point of view, the Munda languages, of which Santali is the biggest member, are peculiar: in Santali there are no genders, - no masculine, feminine, neuter. Their nouns are either animate or inanimate endowed with a soul or without a soul. The entire animal kingdom is animate, has a soul. The whole of the mineral kingdom is inanimate, without a soul. There are oddities: e.g., the sun, moon, stars are animate. Strangely, the vegetable kingdom - herbs, shrubs, trees, the fungal world - is inanimate, but *with a single exception*, one species of mushroom, the *putka*. The Santal do not know why the *putka* is animate, or so they say. The *putka* is an underground fungus that is gathered for eating just as it appears, a snow-white little ball, in mycology identified by Heim as a *Scleroderma*, well known in Europe. In season it is commonly highly prized as food by the Santal, and much sought for by women and children.

For the last century the Norwegian Lutherans have made a vigorous play to be helpful in India by missionary activity among the Santal. The Rev. P. O. Bodding, a resident of the Santal Parganas from 1890 to 1934, mastered their language and compiled an admirable Santal-English dictionary in five large volumes, pointing out among other things the oddity of *putka*, which enjoyed in the vegetable kingdom the unique attribute of a soul. He could not explain this anomaly, nor did he venture an etymology for *putka*. But in the preface to his dictionary Mr. Bodding observed a noteworthy fact:

> Strangely enough, the Santals use some pure Sanskrit words, which, so far as I know, are not heard in the present day Hindi.

I visited Dumka in the Santal Parganas for the first time in January 1965. The Rev. A. E. Strønstad, Mr. Bodding's successor, and Mrs. Strønstad put me up and Mrs. Strønstad graciously served as my interpreter. We asked elderly and knowledgeable Santal in Dumka and the surrounding villages why *putka* was animate. No one could tell us. Our best informant turned out to be Ludgi Marndi, the widow of a native Lutheran pastor. She told us that there was one entheogenic mushroom.[6] Was it the *putka*? No, not at all. It was merely *ot*', 'mushroom' of the soulless class. No one was able to find an example of this inebriating mushroom, but the description (big, growing only in dung mostly of cattle, and white reaching an intense cream color in the umbolate center) tallied with *Stropharia cubensis*. Neither were there any *putka* at the time of my visit: they would come after the monsoon broke. Ludgi Marndi and some other informants suggested that the *putka* was animate because it was found regularly in the sacred grove of *sarjom* trees near every village. (Santali *sarjom* = Hindi *s&amacr;l* = *Shorea robusta*.) But the sacred *sarjom* trees were not animate so why should a mushroom growing from their roots be? Furthermore, the *putka* grew also in mycorrhizal relationship with other species of trees. Ludgi Marndi seemed an especially good informant and just before we were leaving for New Delhi, defeated as we thought, I asked if I might talk with her again. We went over the same ground. Suddenly she leaned forward across the table to Mrs. Strønstad and in a whisper (as translated to me) said that she would tell her why she thought the *putka* were animate: 'You must eat them within hours of gathering *for they will soon stink like a cadaver*.' She spoke under considerable emotion. We knew not what this meant but at once I jotted down her translated words in my notebook and her remark appeared later, somewhat toned down, in the paper[7] that Heim and I published.

My 1965 visit was followed by another with Heim in July-August 1967, he flying from Paris to Calcutta and I from New York. We started our quest in the Simlipal Hills and the village of Bisoï in Orissa, where the Santal and their close linguistic kin the Ho intermix, as well as several other peoples. Again we questioned the natives about why the *putka* were animate. In Nawana in the Simlipal Hills I spent the evening with Ganesh Ram Ho, the chief of the village, and he, as Ludgi Marndi had done, volunteered the information that there was an entheogenic mushroom, and his description tallied with Ludgi's; his testimony confirmed that it was probably

Stropharia cubensis or a close cousin. (That these two excellent informants volunteered to speak of an inebriating mushroom, doubtless *Stropharia cubensis*, is a lead not to be neglected: it may have played a part in the cultural past of the Santal and of Soma.) But, just as before, it was '*ud*' and soulless. '*Ud*' is 'mushroom' in Ho.

We published the account of our trips to the Santal country in *Les Cahiers du Pacifique*, #14, September 1970. Kramrisch in time saw our paper and she grasped immediately that the *putka* of the Santal was the *P&umacr;tika* of the Br&amacr;hmaṇas, of the Pravargya sacrifice and the Mah&amacr;v&imacr;ra pot.[3] The *P&umacr;tika* had been the surrogate for Soma and naturally it would possess a soul! Kramrisch deserves a rich accolade for discovering that Santali *putka* was a loanword from the Sanskrit *P&umacr;tika*. When Soma was being abandoned, probably over a long period that ended shortly after B.C. 1000, the *P&umacr;tika* took its place, not as an entheogenic drink like Soma in the earlier sacrifice but as a component with the clay in the ceremonial firing of the Mah&amacr;v&imacr;ra vessel. Its stench (of which Ludgi Marndi had spoken) was turned into fragrance when the pot, held by tongs, was fired in the course of the rite. No one had ever known what plant it was. We now know that, like Soma, it was a mushroom, but a common mushroom, and it possessed divine qualities though less than Soma's.

In Santal culture not only is the *putka* animate, endowed with a soul: it possesses another of Soma's attributes. The belief is apparently universal among the Santal that the *putka* is generated by (mythological) thunderbolts.[8] Long after the Brahmans have lost any use for or knowledge of this mushroom, and have lost all special contact with the Santal, these humble, hardworking people, untouchables, still believe that the *putka* is procreated by the lightningbolt, as the Vedic Brahmans believed that Soma was procreated by the Vajra of Indra, or Parjanya, the god of lightning. Here is another manifestation, another proof, of the breathtaking cultural intensity millennia ago of the religion of the hierarchs of the Aryans. The lightningbolt was thought of as the sperm, the spunk, fecundating the soft mother earth with the entheogenic mushrooms.

The Santal believe there are two kinds of *putka*, the *hor putka* and the *seta putka*, one smooth and the other rough. Heim said the two kinds were merely different stages in the life cycle of the one species. The *hor putka* is the 'man *putka*,' not in the sense of male but of a human being, or of the 'Santal' whom they naturally regard as *par exellence* the human being. The *seta putka*, which is rough, is the 'dog *putka*,' the dog not being despised as it is in Hindu culture. A few of the Santal spoke to us of a third *putka*, the *rote putka* or 'toad *putka*.' Most Santal did not recognize this term and of those who did, most could not say what kind of mushroom it meant. But when we were in Kathikund, a village in the Santal Parganas, we witnessed from our veranda a violent midday thunderstorm and within hours and then throughout the night a host of puffballs appeared on the plain before our bungalow. One of our Santal companions told us with assurance that these were indeed *rote putka*. In this instance the puffball was *Lycoperdon pusillum* but probably any other puffball coming in response to a thunder shower would be a *rote putka*. In short, the *rote putka*, which is not eaten by the Santal, is a false *putka*. ... The entheogenic mushrooms of which Ludgi Marndi and Ganesh Ram Ho had told us, probably *Stropharia cubensis*, are not *putka*: they are merely *ot*', or *ud* in the Ho language, enjoy no grammatical distinction in the languages, and so far as I learned no distinction in folklore. But it is imperative that this be explored much further. Does its entheogenic virtue account for the colored geometrical designs, endlessly varied, that decorate the exteriors of many Santal houses?

Throughout our visits to the Santal country the people we spoke with said that pigs dug for the *putka*, thus confirming what the canonical P&amacr;li Commentary on the *Ud&amacr;na* says of *s&umacr;kara-maddava* (p. 27, *infra*). But I was seeking a quotation and after returning to New York the Rev. Johannes Gausdal, a retired missionary living in Oslo, put me in touch with Mr. Gora Tudu, principal of Kaerabani High School, and we asked Mr. Tudu through Mr. Gausdal whether swine sought out the *putka* in the forest. Here is what he replied:

> Whether the pigs eat *putka* or not? In this case also I got some *putka* from the forests. I tried them on a few pigs - the old *putka* were not liked, but the new ones seemed to be delicacies of the pigs. They ate them with relish. Also in the forest I found at several bushes where *putka* usually come up several marks of upturned earth, indicating that the pigs had been digging for the *putka*. [Letter in my *Munda* file]

I was careful not to divulge the reason this question was being asked. There are a number of genera of underground fungi divided among scores of species, and I should be surprised if they all drew pigs but perhaps they do.

Mr. Gausdal asked also about the smell of aging *putka*. Mr. Tudu replied, with unconscious humor:

> I collected some *putka*, both *hor putka* and *seta putka*, and put them in dishes in dry condition as well as wet, just to see what the smell would be like after decomposition. In both the smell emitted was that of decomposing wood material, not at all bad in the sense of any blooded being. The smell was never too strong or filthy. The worst I could compare, the smell was that of rotting jute in muddy water.

Kramrisch tells me that rotting jute in muddy water creates a fearful stench. Mr. Tudu possesses the endearing quality of dirt farmers everywhere: their fondness for the smell of dung heaps, for example, is powerfully colored by what dung means for the crops. The earthy smells of farm yards also possess a likeable integrit.

The Gausdal-Gora Tudu correspondence was conducted in Santali, but my questions and his answers to them were in English.

We know that the Santal have not always lived where they do now. Six hundred years ago they lived to the west of Benares on the Chot&amacr; N&amacr;gpur plateau, and tradition has it that long before then the Santal had lived much further to the West, just where no one knows, but possibly near the ancient center of Brahmanical sacrifices, where they could have had close relations with the Aryans, perhaps serving them before and through the shift from Soma to the *P&umacr;tika*. This would also explain the other Sanskrit words in Santali that Mr. Bodding notes. Indeed he remarks in his preface to his Santal Dictionary that 'the description of the Dasyus in the Vedas and the Mah&amacr;bh&amacr;rata seems to be adaptable to many a Santal.'

III. The death of the Buddha

Having completed the Santal interpolation, we will now revert to the text of the *D&imacr;gha Nik&amacr;ya* as translated by the Rhys Davids.

After the discussion of the *s&umacr;kara-maddava*, the Rhys Davids translation continues with an astonishing development:

> §20. Now when the Exalted One had eaten the rice prepared by Cunda, the worker in metals, there fell upon him a dire sickness, the disease of dysentery, and sharp pain came upon him, even unto death. But the Exalted One, mindful and self-possessed, bore it without complaint. [Chap. IV]

This was a disconcerting turn of events, since the Omniscient One has but lately said that he sees no one, save a Tath&amacr;gata, who can properly assimilate the *s&umacr;kara-maddava*, which he has just eaten. If the circumstances were invented, as Bareau thinks, what a strange set of circumstances for utterly devoted followers of the Buddha to have invented! The mushrooms, now that we know precisely, were sound and there was never a risk: moreover, aged *P&umacr;tika* would declare their age by their stench! And Cunda was a responsible man to buy and cook them. However, let us remember that in the upper Hindu castes where the Buddha had been brought up and lived out all his early life, even though he was now free from food tabus and caste distinctions, all mushrooms would be shunned as inedible; but here, at a critical moment of his life, he was being offered *P&umacr;tika*. Did Cunda know the role of the *P&umacr;tika* in the religion of the twice-born castes? Did he perhaps know it by rumor, inaccurately? Or did he not know it at all and was he serving these mushrooms solely for the excellent reason that they were fresh and in season? It is clear from the testimony of the *D&imacr;gha Nik&amacr;ya* that the attack suffered by the Buddha was sudden; it was violent; it alarmed the whole company; it was virtually over quickly, for not long afterward the Buddha instructed the faithful &Amacr;nanda that they should walk on to Kusin&amacr;r&amacr; close by. But what could be more natural than a violent reaction in one brought up as a kṣatriya to consider mushrooms inedible? And with his large intestine being chronically inflamed with dysentery, his diarrhoea was a natural sequence. 'Dysentery' is a translation of the P&amacr;li *lohita-pakkhandika*, which means 'bloody flux' in old-fashioned English.

The account in the *D&imacr;gha Nik&amacr;ya* is as though written to order for this explanation. Two quatrains, apparently independent of each other, are inserted in the text of the *D&imacr;gha Nik&amacr;ya* (§20, p. 139) at this point. Buddhaghoṣa adds a note: 'It should be understood that these are the verses by the Theras [Elders] who held the Council' the Council that took place at R&amacr;jagṛha, at which some months later the initial plans were laid for mobilizing detailed recollections of the Buddha's teachings and for organizing the Buddhist religion. The first quatrain shows how those present murmured against Cunda, and, according to the second, there was also murmuring about the mushrooms. Here are the quatrains in the Rhys Davids translation:

> When he had eaten Cunda's food,
> The copper-smith's - thus have I heard -
> the bore with fortitude the pain,
> The sharp pain even unto death.
>
> When he had eaten, from the mushrooms [=*s&umacr;kara-maddava*] in the food
> There fell upon the Teacher sickness dire,
> Then after nature was relieved the Exalted One announced and said:
> I now am going on to Kusin&amacr;r&amacr;

After the episode the Exalted One went out of his way to exonerate Cunda of blame, thus making even more tenable my explanation of his illness. For if Cunda had been guilty of negligence in choosing the mushrooms, why should the Omniscient One have exonerated him?

> 42. And the Exalted One addressed the venerable &Amacr;nanda, and said: - 'Now it may happen, &Amacr;nanda, that some one should stir up remorse in Cunda the smith, by saying: - "This is evil to thee, Cunda, and loss to thee in that when the Tath&amacr;gata had eaten his last meal from thy provision, then he died." Any such remorse, &Amacr;nanda, in Cunda the smith should be checked by saying: - "This is good to thee, Cunda, and gain to thee, in that when the Tath&amacr;gata had eaten his last meal from thy provision, then he died." From the very mouth of the Exalted One, Cunda, have I heard, from his own mouth have I received this saying: - "These two offerings of food are of equal fruit, and of equal profit and of much greater fruit and much greater profit than any other - and which are the two? The offering of food which, when a Tath&amacr;gata has eaten, he attains to supreme and perfect insight; and the offering of food which, when a Tath&amacr;gata has eaten, he passes away by that utter passing away in which nothing whatever remains behind these two offerings of food are of equal fruit and of equal profit, and of much greater fruit and much greater profit than any others. There has been laid up by Cunda the smith a karma redounding to length of life, redounding to good birth, redounding to good fortune, redounding to good fame, redounding to the inheritance of heaven, and of sovereign power." In this way, &Amacr;nanda, should be checked any remorse in Cunda the smith.' (p. 147-8)

Bareau concedes that Cunda and P&amacr;v&amacr; may be original elements but, if so, thinks that they are the sole original elements in the narrative of the Buddha's stay in P&amacr;v&amacr;:

> Deux siècles après le Parinirv&amacr;ṇa, ces deux noms, ici P&amacr;v&amacr; et Cunda, étaient les deux seuls éléments anciens, peut-être même historiques, de l'épisode du dernier repas du Buddha. Aucun souvenir n'avait donc été conservé ni des incidents qui avaient pu s'y produire ni de la nature précise des aliments qui avaient été servis alors au Bienheureux. [Tome I, p. 258 in his *Recherches sur la biographie du Buddha*, Ecole Française d'Extrême Orient]

Perhaps in the light of our discoveries Bareau may grant more to the history of the Buddha's Last Meal in P&amacr;v&amacr; as told in the *D&imacr;gha Nik&amacr;ya*. Too many had witnessed the episode with the mushrooms to permit the Theras to suppress it: his sudden illness had provoked too much talk.

Here is the account of the Buddha's death according to the *D&imacr;gha Nik&amacr;ya*, Chap. V,

> 1. Now the Exalted One addressed the venerable &Amacr;nanda, and said: - 'Come, &Amacr;nanda, let us go on to the S&amacr;la Grove of the Mallas, the Upavattana of Kusin&amacr;r&amacr;, on the further side of the river Hiranyavat&imacr;.'
> 'Even so, lord!' said the venerable &Amacr;nanda, in assent, to the Exalted One.
> And the Exalted One proceeded with a great company of brethren to the S&amacr;la Grove of the Mallas, the Upavattana of Kusin&amacr;r&amacr;, on the further side of the river Hiranyavat&imacr;: and when he had come there he addressed the venerable &Amacr;nanda, and said:
> 'Spread over for me, I pray you, &Amacr;nanda, the couch with its head to the north, between the twin S&amacr;la trees. I am weary, &Amacr;nanda, and would lie down.'
> 'Even so, lord!' said the venerable &Amacr;nanda, in assent, to the Exalted One. And he spread a covering over the couch with its head to the north, between the twin S&amacr;la trees. And the Exalted One laid himself down on his right side, with one leg resting on the other; and he was mindful and self-possessed.

In a note on this passage the Sinhala commentator added an explanation:

> Tradition says that there was a row of S&amacr;la trees at the head of that couch, and another at its foot, one young S&amacr;la tree being close to its head, and another close to its foot. The twin S&amacr;la trees were so called because the two trees were equally grown in respect of the roots, trunks, branches, and leaves. There was a couch there in the park for the special use of the (periodically elected) chieftain of the Mallas, and it was this couch which the Exalted One asked &Amacr;nanda to make ready. (Ftnt. p. 149)

In the last watch of the night the Buddha died, precisely as he had been predicting for three months, since he was in Vai&sacute;ali.

There have been individuals in various parts of the world, and especially among the holy men of India, who have acquired by 'concentration' (*sam&amacr;dhi*) control over some of the muscles that ordinarily function in response to stimuli beyond the human will. A. L. Basham has remarked on this in *The Wonder That Was India*, p. 327:

> The ancient mystical physiology of India needs further study, not only by professional Indologists, but by open-minded biologists and psychologists, who may reveal the true secret of the yog&imacr;. For whatever we may think about his spiritual claims there is no doubt that the advanced yog&imacr can hold his breath for very long periods without suffering injury, can control the rhythm of his own heartbeats, can withstand extremes of heat and cold, can remain healthy on a starvation diet, and, despite his austere and frugal life and his remarkable physical contortions, which would ruin the system of any ordinary man, can often survive to a very advanced age with full use of his faculties.

Basham fails to mention that occasionally death is the goal of this 'concentration,' but there is no reason to question that death can be the purpose of such an act of will. In recent years, when death has been the end result of this manifestation of will power, *mah&amacr;sam&amacr;dhi* has sometimes been the term used when speaking of it.

The Buddha predicted the day of his death three months before and thenceforward announced freely the time and place of his own extinction. After his Last Meal the narrative says that on his initiative he walked the short distance to Kusin&amacr;r&amacr;. Since the time of his death, no Hindu, no Buddhist, has ever suggested that he died of mushroom poisoning. His death has not provoked discussion among Buddhists. Knowing as we now do what the mushrooms were that Cunda served, they could have provoked a stomach upset in a Hindu mycophobe but they could not have caused his death. He died of his own will power, of his own *mah&amacr;sam&amacr;dhi*. Or, rather than provoking his own death, did he not use yogic power, under trying circumstances, to postpone his translation to *nirv&amacr;na* until he had reached his place of choice?

The surrogate for Soma explains and justifies the extraordinary words used by the Buddha in limiting to himself alone this dish. By consigning to a hole the surplus *P&umacr;tika*, he showed himself familiar with its everyday properties. Now that we know the precise properties of this mushroom, its etymology as cognate with 'putrid' is clarified,[3] and its strong link with Soma is a good explanation for the Santal belief that it is generated by the divine lightningbolt.

Up to this point we have concentrated on only one source - the canonical P&amacr;li Text of the *D&imacr;gha Nik&amacr;ya* - for our details about the life of Buddha. It is the Holy Scripture of the Theravadin branch of Buddhism with its headquarters in &Sacute;r&imacr; Laṅka. There are, in addition, five other master recensions of his life, four in Chinese and one in Sanskrit. All five mention the stop in P&amacr;v&amacr; and name Cunda as the host there, but none of them mentions *s&umacr;kara-maddava*. An obvious explanation for this omission is that the Chinese are natural mycophiles: they eat with relish all kinds of edible mushrooms and they know their mushrooms. They would not understand why the Buddha honored the *P&umacr;tika*, saying he alone could digest it. For the Chinese all this would have been incomprehensible.

The Buddha and his followers were mostly Hindus of the upper castes who had withdrawn from obedience to the Hindu religion. When the Theras assembled at R&amacr;jagṛha, they were inevitably, even if they were rebels, heirs to the infinite complexity of habits, practices, subtle ways of thinking and feeling of the Brahmanic religion. When Buddhism became a world religion, it liberated itself from the Brahmanic religion and this included the mighty tradition of Soma and the Vedic hymns, and of course from the less powerful hold of the *P&umacr;tika*. In the early days of Christianity, before it became a world religion, the pull of Jewish ways such as circumcision and the ban on pig-meat exerted influence on Jewish converts to Christianity, and the early Church faced a parallel conflict.

IV. The Buddha's last meal

The episode at P&amacr;v&amacr; lends itself to various explanations; the written record contains a number of anomalies. If we were to offer the solution that we think is most likely, here it is.

There is only the Commentary on the *Ud&amacr;na*, which Buddhaghoṣa presented as hearsay, to show that Cunda the &sacute;udra knew of the use made by the Brahmans of the *P&umacr;tika*. Cunda certainly knew this mushroom as a universal favorite among mushroom eaters when it was in season and it was in season right then: he was taken aback when the Buddha recognized the mushroom and asked him, in astonishing language unfamiliar to his ears, to serve them to the Buddha only. Cunda had done himself proud in assembling mushrooms for the whole company, and now he was forbidden to give them to the guests or even to himself.

Shortly after the Buddha had eaten his mushrooms with rice he fell violently ill. This must have caused Cunda consternation and chagrin. Alarm was felt, and there was murmuring against Cunda and the mushrooms in the assembly, for all or almost all were twice-born men and had been indoctrinated against mushrooms. We can imagine Cunda's embarrassment but we have no information: an opaque cloud of silence falls over him.

In the *D&imacr;gha Nik&amacr;ya* the Buddha exonerates Cunda, somewhat stiltedly under the circumstances. Perhaps everyone remembered that the Buddha had spoken up for Cunda and many had heard him but none could recall what precisely he had said. Someone seems to have drafted the paragraph much later. The fitting exoneration of Cunda demonstrated the thoughtfulness and the nobility of the Buddha under most trying circumstances.

Was not '*s&umacr;kara-maddava*' introduced in place of *P&umacr;tika* at R&amacr;jagṛha to avoid confusing people as to the Buddha's attitude toward the Old Religion? He showed an attitude toward the *P&umacr;tika*, and he reacted to them, in a way that we today, under the circumstances, can understand for the first time.

And as for the diverse explanations in the two canonical Commentaries for *s&umacr;kara-maddava*, they may have been introduced at R&amacr;jagṛha also, or perhaps more likely late in A&sacute;oka's reign when the need for an explanation became increasingly felt by the Buddhist community. No theological importance was ever given, then or later, to the P&amacr;v&amacr; episode because, after all, the Buddha was under acute stress at the time, what with his illness, his imminent extinction freely predicted since he was in Vai&sacute;ali three months before the episode at P&amacr;v&amacr;, and the unexpected dish of *P&umacr;tika* that suddenly confronted him. There had been far too much talk among those present to suppress the episode, but obviously the *P&umacr;tika* was not to be identified plainly. The *s&umacr;kara-maddava* was a way to tell the truth but still to interpose obstacles to its understanding. The word may have been a neologism invented *ad hoc*.

Now we see for the first time in how dramatic a predicament the Brahman proscription on mushrooms for the twice-born castes accidentally involved the Buddhist religion at the very moment of its birth. We still do not know we will probably never know when that proscription came into force, perhaps over centuries while the Vedic hymns were being composed, or possibly when the hierarchs among the Brahmans learned of the entheogenic virtues of *Stropharia cubensis* as known to the lower orders living in India, or when Soma was finally abandoned and the *P&umacr;tika* adopted as its surrogate. But we do know how effectively the Buddhist Theras fudged the facts in the *D&imacr;gha Nik&amacr;ya*, until an inquirer 2,500 years after the event appeared, assembled the evidence, and with the help of Georg Morgenstierne, Roger Heim, Stella Kramrisch, Wendy Doniger O'Flaherty, and above all of the Santal people, fitted together the jigsaw pieces.

V. The Indus Valley and Kashmir

When we published *SOMA Divine Mushroom of Immortality* in 1968 I pointed out in it that in the 1028 hymns of the ṚgVeda there was never a mention of the blossoms, fruit, seed, leaves, branches, bark, or roots of the plant - a telling clue where to look for the divine herb. But there was another botanical fact that deserved full recognition, but I had not yet focussed on it.

Botanists divide plants between phanerogams and cryptogams. The phanerogams include all flower- and seed-bearing plants, whether trees, shrubs, creepers or climbers, herbs and grasses, whether cultivated or uncultivated. The cryptogams are lower orders of vegetation, less developed along the evolutionary trail, and the mushrooms are the cryptogams that interest us. Only in recent centuries have three or four species out of thousands lent themselves to commercial exploitation, and a meager handful also to expensive cultivation in laboratories. In Aryan times, in the Indus Valley and Kashmir, there was the widest variety of climate, owing to the variety of accidented terrain therein - lofty mountains, low lying plains, valleys, wetlands, arid stretches - and any needed phanerogam could probably have been grown in some part of that large country. *But only those mushrooms grew there that the country produced spontaneously*. Since we know that the supply of Soma was limited at best to the mountains and must have been further reduced when the monsoon failed, conforming to what we know about Soma in Vedic times, this points to the entheogenic mushroom *Amanita muscaria* for their Soma. That the birch and also the conifers act as hosts to *A. muscaria* was not realized by anyone among the Aryans, and therefore no one thought of planting the host trees to see whether by this means man could thus increase the yield of the holy plant.

Other fungal entheogens grow at the lower levels. They come in cattle dung, are easily identified and gathered, and are effective. But they fail to conform to Brahman practices: they are known to tribals and sudras. Soma on the other hand exacts self-discipline of the priests, a long initiation and training: it is, for proper exploitation, an affair of a priestly *élite*. But the possible role of *Stropharia cubensis* growing in the dung of cattle in the lives of the lower orders remains to this day wholly unexplored. Is *S. cubensis* responsible for the elevation of the cow to a sacred status? And for the inclusion of the urine and dung of cows in the *pañcagavya*? And was that a contributing reason for abandoning Soma? Given the ecological conditions prevailing in the Indus Valley and Kashmir, only a few of the Aryans could know by personal experience the secrets of the Divine Herb. The cult of Soma must have been shaped by the peculiar circumstances prevailing in the area, but ultimately those circumstances must have doomed that cult. Today it lives on in India only as an intense and glowing memory of an ancient rite.

Under the British Raj the rich and diverse vegetation of India was admirably studied, and George Watt's encyclopaedia *Dictionary of the Economic Products of India*, 1889-1896, in eleven volumes, edited and partly written by him, is a major legacy of the British rule in India. However, the mycophobic British did little to advance knowledge of mycology, and the Hindus nothing. No one ever suggested a mushroom for Soma, let alone *A. muscaria*. Our *SOMA* came out in 1968 but no *A. muscaria* since then has yet been found in Pakistan or Kashmir: there have been numerous reports of finds but voucher specimens have not been deposited in herbaria. Dr. Roy Watling, mycologist of the Royal Botanic Garden of Edinburgh, spent three weeks in the field in 1978 on a general survey of the Kashmir area, in the vicinity of Srinagar. He collected in stands of birch in two areas but he arrived there late in the growing season and moreover the season was dry. In his printed report[9] he writes, 'The species *A. muscaria* is almost certainly native to the *Betula*-zone of northern India.' There he found *Betula utilis* from 9,000 feet up to the timber line at 10,500 feet but no *A. muscaria*. In the Northwestern Himalayas the birch grows intermixed with Rhododendron in scrub-vegetation up to 11,500 feet.

We may think we are feeling the frustrations of the Aryans but by comparison with them we are making only lackadaisical efforts to find a few voucher specimens, whereas the Brahmans must have developed urgent need for quantities of fruiting bodies to dry, and then to reflate, and bring to the pressing stones. Their needs must have been constantly increasing with the increasing population. Whatever may have been the case later, the relations at first with the natives were surely hostile. The natives seem to have come to occupy the intermediate mountain heights, precisely where *A. muscaria* grows and where the ṚgVeda time and again says Soma grows. As we know from the *&Sacute;atapatha Br&amacr;hmaṇa*, the Brahmans depended for their Soma supplies, in large part at least, on the natives living in the mountains. The supply depended on the weather and the state of the relations with the natives, whereas the needs were swelling with every generation. The Brahmans must have found it in their interest to cultivate the Dasyus and the Dasyus would have found it advantageous to discover every spot where *A. muscaria* grew, above all the stands of birch but also other host trees. (*A. muscaria* has been reported lately from Tamilnadu, especially from the Nilgiri Hills, in Southern India, but its presence there has been attributed by mycologists to plantings of exotic conifers in the past century.) Most of the Soma sacrifices must have used make-do phanerogamic substitutes and in the post-Vedic Br&amacr;hmaṇas and other writings we learn how the priests from early times faced this scarcity with such make-do plants.

The Brahmans probably continued to trade with the mountains of Afghanistan seeking Soma, and with the Hindu Kush, but there is no knowing whether these tribesmen were friendly, perhaps intermittently. The *Afghanistan Journal* 6.2, 1979, announced the finding of *A. muscaria* in Nuristan, in the Shetul Valley high in the Hindu Kush in the extreme northeast of the country. The authors, Gholam Mochtar and Hartmut Geerken of Kabul, talked with three old codgers, ostensibly *habitués* of the "ravens' bread," claimed to be *A. muscaria* from which an inebriating concoction is made. The episode is insufficiently documented to permit conclusions about its bearing on *Amanita muscaria* and the Soma question. Their report antedates the Russian invasion.

The use of substitutes by the Aryans must have been a reluctantly adopted practice from the start. They are mentioned for the first time in the last batch of hymns incorporated into the canon, Mandala X 85 through to the end, 191. In *SOMA* we failed to take into consideration these hymns of Mandala X, since they were admitted to the canon at a late stage, shortly before the Vedic age ended. But some years ago Professor Clifford Wright, in a lecture delivered at Cambridge University, took the position that many of those hymns, the last to be admitted to the canon, on strong stylistic grounds were by no means the last to be composed. There is a verse in these hymns that speaks of the substitutes. That hymn may well have been composed centuries earlier:

> ṚgVeda X 85.3: One thinks one drinks Soma because a plant is crushed. The Soma that the Brahmans know - that no one drinks.

This conforms to our present thinking: the scarcity of Soma was not to be explained by the spread of the Aryans southward, then eastward down the Yamun&amacr; and beyond the confluence with the Ganges. The scarcity had always existed, and the make-do substitutes had been a chronic problem.

6. 'Entheogen' is a word devised by some of us for those plant substances that inspired Early Man with awe and reverence for their effect on him. By 'Early Man' we mean mankind in prehistory or proto-history, before he could read and write, whether long long ago or since then or even living today in remote regions of the earth. 'Entheogen' (or its adjective 'entheogenic') has the advantage that it does not carry the odor of 'hallucinogen,' 'psychedelic,' 'drug,' etc., of the youth of the 1960s. Memorandum by Walpola R&amacr;hula of the early sources for the meaning of *s&umacr;kara-maddava*

The original Canonical P&amacr;li passage from the *Mah&amacr;parinibb&amacr;nasutta* of the *D&imacr;ghanik&amacr;ya*, P&amacr;li Text Society edition (London 1966), Vol. II, p. 127:

> *Atha kho Cundo kamm&amacr;raputto tass&amacr; rattiy&amacr; accayena sake nivesane paṇ&imacr;taṃ kh&amacr;daniyaṃ bhojaniyaṃ paṭiy&amacr;d&amacr;petv&amacr; pah&umacr;tañ ca s&umacr;karamaddavaṃ Bhagavato k&amacr;laṃ &amacr;roc&amacr;pesi: 'K&amacr;lo bhante, niṭṭhitaṃ bhattan'ti.*

Translation:

> Then at the end of that night, Cunda, the smith, having made ready in his house hard and soft delicious food, and also a big quantity of *s&umacr;karamaddava*, announced the time to the Exalted One, saying: 'The time, Lord, has come, the meal is ready.'

In explaining *s&umacr;karamaddava* in this passage the P&amacr;li Commentary of the *D&imacr;ghanik&amacr;ya*, *Sumaṅgalavil&amacr;sini*, P&amacr;li Text Society ed. (London, 1971), Vol. II, p. 568, gives three different opinions:

> *S&umacr;karamaddavan ti n'&amacr;titaruṇassa n'&amacr;tijiṇṇassa ekajeṭṭhakas&umacr;karassa pavattamaṃsaṃ. Taṃ kira muduñ c'eva siniddhañ ca hoti. Taṃ paṭiy&amacr;d&amacr;petv&amacr; s&amacr;dhukaṃ pac&amacr;petv&amacr;'ti attho.* (Colombo ed. of the *Sumaṅgalavil&amacr;sin&imacr;*, Part 1, (1918) p. 395 adds within brackets): [*Eke bhaṇanti: s&umacr;karamaddavaṃ pana muduodanassa pañcagorasa - y&umacr;sap&amacr;canavidh&amacr;nassa n&amacr;mam etan'ti yath&amacr; gavap&amacr;naṃ n&amacr;ma p&amacr;kan&amacr;maṃ. Keci bhaṅanti: s&umacr;karamaddavaṃ n&amacr;ma ras&amacr;yanavidhi, taṃ pana ras&amacr;yanasatthe &amacr;gacchati, taṃ Cundena Bhagavato parinibb&amacr;naṃ na bhaveyy&amacr;'ti ras&amacr;yaṃ paṭiyattan'ti.*]

Translation:

> *S&umacr;karamaddava* means meat available (in the market) of an excellent (first-rate) pig neither too young nor too old. This is soft and fatty. 'Having made it ready': having cooked it well is the sense. (Some say: *s&umacr;karamaddava* is the name for a culinary preparation of soft rice made into a broth with the five products of the cow,[1] just as *gavap&amacr;na* is the name of a culinary preparation. Others say: *s&umacr;karamaddava* is a chemical preparation [elixir]. It is found in the science of chemistry. That chemical preparation [elixir] was made by Cunda thinking that the *parinibb&amacr;na* of the Exalted One might not take place.)

The story of Cunda offering *s&umacr;karamaddava* to the Buddha occurs exactly in the same way in another canonical P&amacr;li text, *Ud&amacr;na*. The *Paramatthajotik&amacr;*, Commentary on the *Ud&amacr;na* (Colombo, 1920), p. 279, in explaining *s&umacr;karamaddava* gives four different opinions:

> *S&umacr;karamaddavan'ti s&umacr;karassa mudusiniddhaṃ pavattamaṃsan'ti Mah&amacr;aṭṭhakath&amacr;yaṃ vuttaṃ. Keci pana s&umacr;karamaddavan'ti na s&umacr;karamaṃsaṃ, s&umacr;karehi madditavaṃsakal&imacr;ro'ti vadanti. Aññe: s&umacr;karehi madditappadese j&amacr;taṃ ahicchattan'ti. Apare pana s&umacr;karamaddavaṃ n&amacr;ma ekaṃ ras&amacr;yanan'ti bhaṇimsu. Tañ hi Cundo kamm&amacr;raputto ajja Bhagav&amacr; parinibb&amacr;yissati't&imacr; sutv&amacr; 'appeva n&amacr;ma naṃ paribhuñjitv&amacr; cirataraṃ tiṭṭheyy&amacr;'ti Satthu ciraj&imacr;vitukamyat&amacr;ya ad&amacr;s&imacr;'ti ti vadanti.*

Translation:

> It is said in the Great Commentary (*Mah&amacr;aṭṭhakath&amacr;*)[2] that *s&umacr;karamaddava* is soft and fatty pork (flesh of pig) available (in the market). But some say: *s&umacr;karamaddava* does not mean pork (flesh of pig), but bamboo shoot (bamboo sprout) trodden by pigs; others say that it is mushroom grown on a spot trodden by pigs; still others have maintained that *s&umacr;karamaddava* is a certain elixir. They say that Cunda, the smith, having heard that the Exalted One would attain *parinibb&amacr;na* that day (lit., today) thought that it would be good if He could live longer after eating this (preparation), and offered it wishing the Master's longevity.

Epilogue

When I began working with Gordon Wasson on *SOMA*, almost twenty years ago, we had, at first, no suspicion that Soma might have been a mushroom: we just wished to collect the texts relating to Soma and look at them with a botanical as well as an Indological eye. It was only when I casually mentioned to RGW the urine-drinking, Soma-drinking episode in the *Mah&amacr;bh&amacr;rata* that he thought of *Amanita muscaria* as a possible identity for Soma, but from that moment on he became increasingly convinced that this was the case. I was certain that the evidence proved Soma was an entheogen (we called it an hallucinogen then), and that it was not a form of alcohol (as had been theretofore widely believed) but was a drug provoking an ecstasy of a very special kind. Here is a truth of great importance in the study of later Indian religion and this was the major contribution that RGW had made to Vedic studies.

I was, however, not yet convinced that Soma was a mushroom. I felt that the arguments rested primarily on the interpretation of adjectives, many of them words for colors, and mythological traits, many of which applied to other gods as well, permitting other interpretations as well as the interpretation that identified Soma with the fly-agaric. As an Indologist, rather than a botanist, I still feel that the broader hypothesis - that Soma was an entheogen - is more significant than the narrower one - that it was a mushroom. Over the years, however, the new evidence that RGW has brought to light, particularly the evidence linking the Buddha's last meal to Soma through the double links of the Vedic *P&umacr;tika* and the Santal *putka*, does in fact make it seem likely that Soma was a mushroom, as RGW believed from the first moment, and, when we recall the religious role of urine mentioned above, specifically the fly-agaric. But each of the three levels of the hypothesis - that Soma was an entheogen, a mushroom, and the fly-agaric - adds a valuable dimension to our understanding of both Vedic and post-Vedic religion.

Abstract

A series of illustrations in a 15th century Timurid manuscript record the *mi'raj*, the ascent through the seven heavens by Mohammed, the Prophet of Islam. Several of the illustrations depict *Bur&amacr;q*, the fabulous creature by means of which Mohammed achieves his ascent, with distinctive features of the *Amanita muscaria* mushroom. *A. muscaria* or "fly agaric" is a psychoactive mushroom used by Siberian shamans to enter the spirit world for the purposes of conversing with spirits or diagnosing and curing disease. Using an interdisciplinary approach, the author explores the routes by which *Bur&amacr;q* could have come to be depicted in this manuscript with the characteristics of a psychoactive fungus, when any suggestion that the Prophet might have had recourse to a drug to accomplish his spirit journey would be anathema to orthodox Islam. There is no suggestion that Mohammad's night journey (isra) or ascent (mi'raj) was accomplished under the influence of a psychoactive mushroom or plant.

Cultural context

The *mi'raj* manuscript

An illustrated manuscript depicting, in a series of miniatures, the successive stages of the *mi'raj*, the miraculous ascent of the Prophet Mohammed through the seven heavens to receive God's instructions for the faithful was produced in 15th century in the city of Herat (Séguy, 1977). This text of the *mi'raj* story is in Turkish, in the Uighur script. The manuscript was purchased, on behalf of the French Ambassador, in 18th century Constantinople, and it currently resides in the Bibliothèque Nationale in Paris, France as *Manuscrit Supplément Turc* 190.

Herat, today in Western Afghanistan, has been a crossroads of trade and culture for hundreds of years and formed an important stop on the Silk Route. When the Arabs captured Herat in 660 CE, it became a center of the Muslim world. The Mongols swept through and took control of Islamic Central Asia in the 13th century, and Herat went into decline after being sacked by Genghis Khan in 1222-1223. However, control of most of Asia by the Mongols soon created an environment of tremendous cultural exchange and Eastern and Central Asian influences became evident in Islamic art. Timur-i Lenk, the Turkic conqueror, better known in the West as Tamerlane, took Herat in about 1393, initiating its greatest era under Timurid rule, when it became a center of science and culture. The *mi'raj* manuscript illustrations are a product of the Herat school, a style of miniature painting that flourished in the 15th century under the patronage of the Timurids.

Bur&amacr;q depicted as *Amanita muscaria* in the *mi'raj* manscript

In the Muslim tradition, the *mi'raj* was preceded by the *isra* or "Night Journey" during which Mohammed traveled overnight from Mecca to Jerusalem by means of a fabulous beast called *Bur&amacr;q*. In some versions, the Prophet's ascent is also accomplished by the agency of *Bur&amacr;q*. According to tradition, at the site of the Temple Mount in Jerusalem, known to Muslims as *Haram esh-Sharif* ("the Noble Sanctuary"), Mohammed ascended through the seven heavens in the company of the angel Gabriel, to receive God's instructions for the faithful. *Bur&amacr;q* is described as being a creature larger than a donkey but smaller than a mule and is usually depicted as an equine creature with a woman's head and sometimes, but not always, with wings (Hajj&amacr;j, 1989; Vuckovic, 2005).

Seale in her visual history of *Bur&amacr;q* (2016) notes that *Bur&amacr;q* is "*a creature not of scripture but of lore*," first appearing in an 8th century biography of Mohammed. The iconography of *Bur&amacr;q* from Persian miniatures to the decoration of Pakistani trucks is such that "*there is no original, no definitive Buraq, but rather an unruly palimpsest of jumbled creeds, kitsch, and sheer artistic caprice.*" Depictions of *Bur&amacr;q* vary from frankly equine to various chimeras mixing human and various animal parts (Seale, 2016). The plethora of literature concerning Muhammad's ascension to heaven "*slipped its scriptural moorings and slid out into poetry and folklore*" and *Bur&amacr;q*'s body became "*a receptacle for the many myths, metaphors, and moral concerns that Islam inherited*."

Several of the illustrations in the Herat manuscript depict *Bur&amacr;q* with the distinctive red and white spotted skin of the *A. muscaria* mushroom, exact in the smallest detail. That is to say, they both share a distinctive shade of red as a background color, which is covered by small circular or oval white patches that have ragged edges and, when aged, a darkened center (Figure 1). The pattern and color for the Prophet's piebald mount could be the result of an imaginative flight of fancy of the artist, unrelated to the appearance of any mushroom. While the suggestion that the Prophet might have had used a psychoactive drug to accomplish his spirit journey would be anathema to orthodox Islam, there is a variety of evidence that supports the possibility that this illustration could represent the translation into art of Central Asian shamanic traditions, in which the Prophet's miraculous heavenly ascent was interpreted by the artist in terms of a spirit journey accomplished by the agency of the fly agaric mushroom. The author will draw on botanical, linguistic, and ethnographic evidence, as well as the history of religious ideas and folklore, to support the conclusion that the depiction of *Bur&amacr;q* with the distinctive features of *A. muscaria* is not the product of chance.

I must make it clear that I am not in any way suggesting that Mohammad's night journey (*isra*) or ascent (*mi'raj*) was accomplished under the influence of a psychoactive mushroom or plant. I am only asserting that, as Islam extended its influence, the *isra* and *mi'raj* narratives were adapted to different cultural milieus. In the case of the Timurid miniatures, an artist may have embellished *Bur&amacr;q* with a hide resembling the skin of a psychoactive mushroom based on local awareness of shamanic journeys accomplished in this way. Although accounts of the *isra* and *mi'raj* are based on a very brief scriptural reference in the Quran, as agents of missionary conversion and as important assertions of Mohammad's divine authority, these narratives "*have been developed and transformed in fascinating ways in the diverse contexts in which the story was told and retold over the course of many centuries*" (Gruber & Colby, 2010).

Nor am I suggesting that Mohammed would necessarily be seen as a shaman rather than a spiritual leader, except in the sense that his spirit journey could be seen as comparable to those accomplished by a shaman, by those for whom the narrative fitted this context. In Central Asia, shamanism was combined with elements of Sufism to adapt to wider Islamic society. To this day, "islamised shamanism" for the purposes of healing and divination, accomplished through personal relations with spirits, continues to exist in Kazakhstan, Uzbekistan, Tajikistan, Kirghizstan, Northern Afghanistan, the Turkoman province of Iran, and the Uygur district of Xinjian province of China (Zarcone & Hobart, 2016).

The mi'raj as an otherworldly journey in the shamanic tradition

The word *mi'raj* means "ladder" in Arabic, which is a ladder in the tradition of Jacob's ladder in the Old Testament story, reaching from earth to heaven with the Angels of God ascending and descending upon it (Vuckovic, 2005). Mohammed's ladder may be compared to the notched tent pole by means of which Siberian shamans are sometimes described as accomplishing their celestial ascents (Stone, 1992). Since the *mi'raj* tradition first attracted critical scholarly attention, a variety of authors have identified the *mi'raj* as drawing on earlier Judaeo-Christian accounts of heavenly ascent such as the *Book of Enoch* and Iranian traditions such as the *Arda Wiraf* narrative (Vuckovic, 2005). In the *Arda Wiraf* narrative, a righteous man is chosen to visit the spirit world by means of a narcotic potion of wine and Cannabis or Henbane (Flattery & Schwartz, 1992) to determine if the existing forms of Zoroastrian of worship were pleasing to God (Haug & West, 1971).

The dependence of the *mi'raj* story on earlier Iranian and Judaeo-Christian narrative traditions, or their common sources, is still maintained along with the assumption that these traditions reflect earlier shamanic traditions widely diffused throughout Eurasia (Culianu, 2001; Séguy, 1977; Vuckovic, 2005). The traditional descriptions of Mohammed's experiences on his journey include a number of elements that are stereotypical of intoxication by hallucinogenic plants. These elements include distortions of the perceived size of objects; iridescent halos around people and objects; multiple images as under stroboscopic light; everything appearing bejewelled; objects veiled in moving patterns; visions of fantastic animals and vegetation; and a generalized intensification of the all the senses (Hajj&amacr;aj, 1989; Séguy, 1977). Key elements of the *mi'raj* story are present in shamanic spirit journeys, including those that have been recorded as typical of the use of *A. muscaria* (Schurr, 1995).

> These include:
> - helping spirits guide the shaman through the spiritual topology of the supernatural world;
> - exploration of the sacred cosmology;
> - information from the supernatural realm is to be reintegrated into the daily lives of group members;
> - on return from the supernatural realm, the shaman relates his visions to those around them and reports discussions with dead kinsmen.

The angel *jibril* (Gabriel) accompanies and guides Mohammed on his journey. Mohammed is taken in turn through the seven heavens and there meets and converses with his ancestors; former prophets such as Adam, Noah, Idris (Enoch), Abraham, Moses, and Jesus. Mohammed returns with the instructions for worship by the faithful and relates the pleasures of the pure in paradise and the punishments meted out to sinners in hell (Culianu, 2001; Vuckovic, 2005).

The extent and diffusion of A. muscaria and its use as an inebriant

Global distribution and usage

Amanita species are widely distributed throughout the planet. *A. muscaria* grows in summer and fall under coniferous and deciduous trees, from the lowland up to the sub-alpine zone. It occurs practically all over the temperate and subtropical zones in Europe, North Africa, South Africa, Asia, Japan, Australia, North America, and in South America (Seeger & Stijve, 1978). Like a number of other mushrooms, the mycelium of the *A. muscaria* cannot establish itself other than in symbiosis with the root system of certain species of trees. In the case of *A. muscaria*, it is particularly associated with the birch and pine, sacred trees throughout Eurasia.

Prior to invading and establishing a Central Asian empire, the original homeland of the Mongols lay on the fringes of Siberia around the Altai Mountains of Siberia, an area rich in pine and birch trees (de Hartog, 2004), the essential symbiotic hosts of *A. muscaria*. The Turkic-speaking Mongols' favored intoxicant is alcohol in the form of the fermented mare's milk or "koumis." The arrival and availability of alcohol has been viewed as displacing the indigenous use of *Amanita* in the 20th century (Salzman, Salzman, Salzman, & Lincoff, 1996) and *Amanita* usage may have been more extensive in the past. Conversely, *A. muscaria* has been used by soldiers as an inebriant in the absence the availability of alcohol (Wasson, 1972).

Prolific reports of the use of *A. muscaria* as an inebriant were recorded among the indigenous peoples of Siberia, by Russian and European traders, missionaries, and explorers from the 17th century onwards (Wasson, 1972). The majority of records of contemporary use of *A. muscaria* as an inebriant by indigenous peoples is confined to reindeer-herding peoples who speak languages in the Uralic family. These include the Samoyedic or Finno-Ugric groups in Western and Northern Siberia and peoples in the extreme east of Siberia who speak isolates, Paleosiberian languages without any known linguistic relationships to other language families, such the Chukchi (Salzman *et al.*, 1996). Riding a horse or reindeer through the sky is a common metaphor for shamanic spirit journeys in Siberian shamanism and sticks with the head of a reindeer or horse and sometimes both are a tool and badge of office for apprentice shamans in Siberia (Stone, 2003). Reliable reports record that "*Ostyak and Vogul tribes in western Siberia and Kamchadal, Koryak, Chukchi tribes in eastern Siberia, still use A. muscaria for shamanistic rites*" (Michelot & Melendez-Howell, 2003, pp. 131-146). However, the contemporary use of *A. muscaria* has also been recorded in Tibet (Müller-Ebeling *et al*., 2000), Afghanistan (Mochtar & Geerken, 1979), Spain (Fericgla, 1992), South Africa (Miller, 2001), and North America, where Peschel (1998) writes of the traditional use of *A. muscaria* by the Ahnishinaubeg (Ojibway) people who live near Lake Superior. Among the indigenous peoples of Siberia, *A. muscaria* also has medicinal uses as a tonic or to help the elderly sleep (Lincoff, 2005; Saar, 1991). There is artifactual evidence suggesting that historical use in a shamanic context in South America (Furst, 1986) and an awareness of its intoxicating effect in association with altered states of consciousness is indicated in folklore throughout Europe (Fericgla, 2001).

Distribution of mushroom words in Eurasia

In a number of Ugrian languages, mushrooms, and in some cases, the *A. muscaria* specifically, are referred to as *pânkh* in Mansi (obsl. Vogul) *pango*, *panga* (Mordvinian), *pongo* (Cheremis), and in northern Mansi *pânkh* also means "intoxication, drunkenness" (Eliade, 2004). All of these words have the same roots as words in Indo-European (IE) languages such as the Spanish *hongo*, mushroom, English "fungus" and "sponge," from Latin *spongia*, Greek *spongos*. The same IE root is evident in words for mushroom in languages of the Indian subcontinent *khumb(&imacr;)* and *phung&imacr;* (Sindhi), *(k)humb(&imacr;)*, (Hindi) and in Afghanistan Pashto: Waziri *x&omacr;mba* (Morgenstierne, 1957). This root is also evident in the modern English term "(s)punk" for tinder derived from dried tree fungus, *Polyporus fomentarius*. Wasson (1972) cites several references in the Vedic scriptures to *soma*, the sacred drug of Hindu scriptures dating to the third millennium BCE, which he believed to be *A. muscaria*, as the "mainstay of the sky."

In Graves' study of proto-religions in Central Asia, he supplies a *panga*/*pongo*/*hongo* type word list, which he links not to fungus/mushroom, etc., but to a Chinese deity called *P'an Ku* who is "a pillar of the sky." *P'an Ku* swells from an egg-shape until he supports the sky above the earth like a mushroom (Graves, 1994). Stone (1992) discusses *A. muscaria* as Axis Mundi, the white speckles on the mushroom cap-like stars on the dome of the heavens. The wide historical and geographical dissemination of *(s)pong*-type mushroom words, in both Uralic and IE languages, from Western Europe to Siberia and the Indian subcontinent, suggests an extremely ancient Pan-Eurasian cultural distribution of the use and knowledge of fungi, possibly with shamanic roots.

Although in Finno-Ugric languages, *pango*-type words are specifically associated both with *A. muscaria* and words relating to intoxication in general (Balázs, 1996), it is possible that the original reference is to the shape of the growing mushroom's cap, in words meaning "hump," "bump," "ball," and "sphere" as in Sanskrit in which *kumbha* means "hump" (Morgenstierne, 1957). In Hungarian, *gomba* is "mushroom;" *gomb* is "button" or "knob;" and *gömb* is "ball," "orb," "bellshaped," and "globular" (Országh, 1987). In Hungarian, 16 names refer expressedly to *A. muscaria*, including several which refer to its power to intoxicate, such as *bolondgomba*, "crazy mushroom," *táncgomba*, "dance mushroom," *bukfencgomba*, "somersault, crazy mushroom," and also *mesegomba* "mushroom of fairy tales" (Zsigmond, 2003). Hungarian contains many words of clearly Turkic origin and claims for Hungarian as both a Finno-Ugric and Turkic language have both been made. Certainly, there was close contact between Turkic and Finno-Ugric speakers at some point in the emergence of the modern Magyar (Hungarian) peoples.

Indications of the antiquity of *A. muscaria* usage

Bronze Age petroglyphs, discovered on the Pegtymel River in North-Eastern Siberia, depict human figures with mushroom caps for heads or above their heads (Devlet, 2008; Golovnev, 2001). The petroglyphs have been quite logically associated with use of *A. muscaria*, which continues there among the indigenous Chukchi peoples, in an unbroken tradition to this day (Devlet, 2008) and are featured in the film *Pegtymel* (2001) by Dr. Andrei Golovnev, Arctic anthropologist and filmmaker and a leading expert on indigenous peoples and cultures of the Russian North. The illustrations of petrogylphs from the Pegtymel region used are taken directly from the ethnographic film *Pegtymel* (2001), made by Professor Andrei Golovnev, member of the Russian Academy of Sciences, and have been converted to black and white for clarity. An additional source for examples of mushroom iconography in the Pegtymel petroglyphs can be found in Devlet (2008). A discussion of questions of interpretation and illustrations of the Pegtymel' (sic) petroglyphs can be found in PART III, PEGTYMEL' PETROGLYPHS, in Kiriak (2007). A short discussion of the petroglyphs and illustrations can also be found in the study of Gosso and Webster (2014). These petroglyphs depict what may be either anthropomorphic mushroom spirits, as experienced in a state of mushroom intoxication, or individuals themselves under the influence of hallucinogenic mushrooms, so indicated by placing a mushroom motif in place of or above their heads (Figures 2-5).

Barkalaja (1997) has conducted field research among the Khanty (obsl. Ostyak) peoples, who inhabit a vast area of swampland in North-Western Siberia. According to Barkalaja (1997), for the Khanty, *pong* (*A. muscaria*) is the intermediary between the shaman and God. *Pong* communicates by turn questions and the answers journeying to the heavens and back. In some regions, the spirit of the Khanty shaman himself travels after eating *pong*. In others, it is not the shaman who sings at a ritual, but the mushroom spirit; the shaman merely repeats the songs sung to him by the spirits of the mushroom. This notion is congruent with that of the Mazatecs, indigenous peoples of Oaxaca, Mexico, who use psychoactive mushrooms of the genus *Psilocybe*. In trance, it is the mushrooms who speak. "*If you ask a shaman where his imagery comes from, he is likely to reply: I didn't say it, the mushrooms did*" (Munn, 1973, pp. 86-122). Among the modern Chuckchi of the Pegtymel region, an elder, describing his visions under the influence of *A. muscaria*, corrects his wife's remark, "*remember you were telling me once that you took* vapak (*A. muscaria*) *and saw dead people*," by saying "*I didn't see them the* vapak *saw them*" (Golovnev, 2001). According to the Chukchi, "*when you take* vapak *you feel as if you are walking, your legs are yours, but the head is another's, the head of the mushroom. You are not a human anymore but a spotty mushroom*, vapak" (Golovnev, 2001). Devlet (2008) reports mushroom-like rock art images from Chukotka, South Siberia, and Central Asia and associates them with ethnological observations of the extant practice of eating *A. muscaria* among the Chukchas. Cheremisin (1997) reports depictions of human figures in mushroom-shaped "headdresses" as widespread in the rock art in Central Asia and in Southern Siberia, in Tuva, the Mongolian Altai, in Northern China, and Inner Mongolia, but challenges their connection with an *A. muscaria* cult. However, the Pegtymel petroglyphs are so evocative of the traditional conceptions of mushroom intoxication by Siberian and other indigenous peoples that any alternative interpretation would need strong evidential support, given the documentation of existing traditions of eating *A. muscaria* in the same location.

Folk use of *A. muscaria* as an inebriant in modern Afghanistan

Contemporary use of *A. muscaria* as an inebriant in Central Asia was discovered in Afghanistan during the 1960s, by Said Ghoulam Mochtar and Hartmut Geerken. They made several mycological expeditions to the Shutul Valley, a side valley of the River Panjshir, which rises in the Mountains of the Hindu Kush to the north of Kabul, in eastern Afghanistan. There they were able to question several older male inhabitants of this secluded mountain valley about the use of *A. muscaria*, which both plays a recreational role and has applications in folk medicine there (Mochtar & Geerken, 1979). Inquiring about its occurrence and use, Mochtar and Geerken were informed that *A. muscaria*, locally called *Nan-e-saghta*, "Raven's Bread" is gathered in the late spring of wet years and dried in the hot sun. In this way, the mushroom is almost permanently preserved. The association of ravens with *A. muscaria* also occurs in Siberian folk tales. A Koryak tale relates how the powers of the mushroom we revealed to the culture hero, Big Raven, by God to achieve a Herculean task. Big Raven says afterward: "*Let the Agaric remain on earth and let my children see what it will* *show them*" (Waldemar, Kasten, & Dürr, 2016, p. 162).

In the Shutul Valley, dried *A. muscaria* is ground to a powder by the inhabitants for its use as an inebriant. They boil the *Amanita* powder with fresh mountain snapweed and soured goat-cheese brine, and in this way produce a well-known local specialty, "Extract of Shutul." In the hamlet of Qaf-e-Changar, at the upper reaches of the Shutul, the calyx-tips of seed-bearing flowers of the black henbane, *Hyoscyamus niger*, are added to the extract. It is used for purposes of therapeutic massage, coming into effect by means of transcutaneous stimulation. An external application of *A. muscaria* is also used by the Khanty of Siberia for treatment of snakebite (Saar, 1991).

During their excursions, Mochtar and Geerken (1979) were able to tape-record the reports of elderly inhabitants of the valley, describing their experiences under the influence of the mushroom.

> - Farid Ahmad (aged around 60 years): "*[around 15 minutes] after I drink the extract, a feeling of weariness and a need for sleep overcomes me. I hear voices, although I am alone in my room.... I laugh about the voices and about myself...*"
>
> - Mustafa (aged around 60 years): "*First, I am very sleepy, then I feel good. I forget sentences.... Once I thought that I was a tree...*"
>
> - Ahmad Kargar (aged about 65 years): "*I have drunk it for many years, yet only once have I had a really bad time. I was anxious and afraid; I ran around in the woods and didn't know who or where I was...*"
>
> - Malang Aziz (aged between 60 and 70 years): "*We don't have much, but we have Raven's Bread. We grind it down to a gray powder and make a concoction of it.... In Winter, when we can't leave the house, we drink it.*"

In the Shutul Valley, the preparation and use of *A. muscaria* would appear to exist only as an archaic practice among the valley's older inhabitants. Mochtar and Geerken (1979) conclude that it should be of great interest to mycologists that these vestiges of a mushroom cult have survived until our day in one remote mountain valley in the Hindu Kush, "and perhaps others elsewhere?"

Bur&amacr;q, shamanism, and the theme of regurgitation

Bur&amacr;q and baraq as Mount of the Shaman

Dankoff (1971) explores the relations in language and myth between the Turkic *baraq* referring to the "mount of the shaman" and the Arabic *Bur&amacr;q*, the fabulous mount by means of which Mohammed accomplishes the *isra* and sometimes the *mi'raj*. He identifies the routes by which the Middle Iranian *b&amacr;rak*, thorough linguistic borrowing, came to designate, on the one hand, the Arabic *Bur&amacr;q* Mohammed's spirit mount and on the other the Turkic *baraq* to designate the "mount of the shaman," a "shamanic animal," or "the shaman himself." In the early 13th century, in Turkey, Syria, and Iran, dervishes of wild appearance gathered around a nominally Muslim spiritual leader called Barak Baba (Karamustafa, 1994). Of special interest is the manner in which Barak Baba received his name. In a version of the story cited by Dankoff, while Saru Saltuk (Barak Baba's spiritual master) was yet a shepherd, Seyyídi Mahmud (Baraq Baba) paid him a visit and placed in his mouth a morsel of food along with some yogurt. This morsel was like a piece of matted cloth, the size of a bean, and stuck to his upper palate. Saru Saltuk at once had a fit of vomiting, and this morsel fell out with his vomit. The prince had fallen into a trance at Saru Saltuk's discourse, and he now ate up the vomit. Saru Saltuk caressed him and called him "my *baraq*" (Dankoff, 1971, pp. 109-110).

Regurgitation in association with mushrooms and shamanism

While eating someone's vomit might appear disgusting to modern western tastes, it was not foreign to Siberian cultures as the following 19th century account makes clear. "*If the Yakut was a good and loving spouse, he would go directly home and eject the contents of his stomach into a vessel of water, which then he placed out* *of doors to cool and collect; and from the rich, floating vomit his wife and children would afterward enjoy a hearty meal*" (Melville, 1885, p. 318). This practice also formed part of the ritual employment of *A. muscaria* as an intoxicant in Siberia. A shipwrecked seaman, who had been rescued by the Siberian Chukchi, with whom he remained some 2 years, described their way of making an intoxicating liquor in this way,

> *... in the summer, mushrooms or fungi were collected in large quantity, and eaten by a man who, like our Indians, prepared himself by fasting for the feast. After eating enormous quantities of the fungi, he vomited into a receptacle, and again loaded up, time and again, and disgorged the stuff in a semi-fermented or half-digested condition. It was swallowed by those who were waiting for the drink; and his urine was also imbibed, to aid in producing a debauch, resulting in frenzied intoxication.* (Bourke, 1891, p. 74)

The theme of regurgitation in association with a spirit helper in the guise of a mushroom turns up in Finnish folklore. According to the Victorian folklorist Keightley (2000), a type of Finnish goblin steals the milk from other people's cows, carries, and coagulates it in his stomach and then disgorges into his mistress's churn. In this connection, Keightley states that there is a species of mushroom which, if it is fired with tar, salt, and sulfur and then beaten with a rod, will cause the woman who owns the goblin to quickly appear and beg to spare him. That is to say, the mushroom's role as an assistant or familiar spirit, by means of which his mistress accomplishes her sorcery, is thus revealed. Siberian shamans view *A. muscaria* consumption as a means of creating assistants to assist them in contacting the supernatural world (Schurr, 1995).

In this connection, it is relevant that, in Norse mythology, Odin by means of transforming first into a snake and then into a bird, steals, swallows, and then regurgitates the "mead of inspiration." He thereby makes it available to man, endowing those privileged to drink it with the gifts of poetic composition. A lesser portion is excreted from his other end for the benefit of a lower class of poet. Among populations using *A. muscaria* for shamanic purposes, transformation into animals is a typical experience of *A. muscaria* intoxication (Schurr, 1995) and in this guise the shaman is able to perform supernatural feats. The recurrent theme in folklore of a magical food that endows men with supernatural talents is certainly a reference to the consumption of psychoactive substances and the talents supported by *A. muscaria* in Siberia include assistance in the recital of epics (Schurr, 1995).

Evidence of *A. muscaria* usage in the Timurid religious milieu

A. muscaria in Tantric Buddhism

The imbibing of bodily fluids and other excrementa is a feature of the esoteric schools of Buddhist and Hindu Tantra, in connection with initiation and transcendental mind states (Crowley, 1996; White, 2003). It is possible that the depiction of *A. muscaria* in the Timurid manuscript as the agency of the Prophet's ascent reflects an awareness of its properties assimilated from Tibetan Buddhism. There is intriguing evidence for the use of *A. muscaria* not only as recorded in contemporary Tibetan shamanism (Müller-Ebeling *et al.*, 2000), but also in the Tantric traditions of Tibetan Buddhism found in Tantra's classical texts (Crowley, 1996; Hajicek-Dobberstein, 1995). Although later largely supplanted by Islam, many Mongols had adopted Buddhism early in the 13th century as they were exposed to the religion in China, Tibet, and Northern India (Nicolle, 1998, pp. 134-140). Ghengis Khan's grandson, Hülegü (1217-1265), the first Khan of the Ilkhanate of Persia, adopted some Buddhist customs. He considered himself a devotee of the Boddhisattva Maitreya (Nicolle, 1998, pp. 134-135), but is primarily regarded as a traditional Mongol shamanist (Heissig, 1980).

Influence of Buddhist and Hindu esotericism on Islamic mysticism

Buddhism was "*the most important civilized religion among the first Il-Khans. Buddhist monks came from China, Tibet and Uighur Central Asia*" (Nicolle, 1998). Hülegü's brother, Kublai Khan (1215-1294), adopted the slightly unorthodox Tibetan lamaist version of Buddhism and made Buddhism the state religion when he became Khan of the Mongols in 1260. Hülegü's grandson, Arghun (1258-1291), "*brought both Buddhist priests* *and men skilled in yogic mysticism from India. It is even possible that Buddhist yogis and the half-shamanist bakshi ascetics in the Il-Khan Court influenced the development of certain later forms of Islamic Sufi mysticism. This in turn influenced aspects of modern Iranian Sh'ia Islam*" (Nicolle, 1998, p. 135).

According to Heissig (1980, p. 4):

> *... through close contact with the Turkic Uighurs settled in the cities, who practised Buddhism, Manichaeism and Nestorianism, ideas from these religions penetrated among the Mongols, above all the Manichaean concepts of light, the figure of Hormusta, the Ahuramazda of the Persians.*

Besides being written in Turkic in the Uighur script, the Timurid illustrated manuscript of the *mi'raj* reveals Buddhist and Zoroastrian (Iranian) influences in its iconography (Séguy, 1977). In Zoroastrian tradition, the conversion of legendary King Vishtasp recorded in the Zoroastrian scriptures to Zoroaster's religious message is achieved when Ahuramazda instructs an angel to carry up to Vishtasp a potion described as "*that fountain of life, for looking into the existence of the spirits, the enlightening food by means of which great glory and beauty are seen by Vishtasp*" (West, 1987). The possible use of *A. muscaria* by the Manicheans, who are condemned in a medieval Chinese text for eating red mushrooms, is cited by Wasson (1972).

Influences from Islam were joined by those from the earlier assimilation of Buddhism and the indigenous shamanistic conceptions of the Mongols. This resulted early in a predominance of syncretistic thought and the fusion of motifs from different religious traditions (Nicolle, 1998, pp. 134-140). The practices of Tantric Buddhism, which were certainly an aspect assimilated by the Mongols (Heissig, 1980), have important elements in common with the antinomian dervish movements and associated figures such as Barak Baba. They included the deliberate flouting of convention as an aspect of religious asceticism, including the eating of forbidden foods, the use of drugs for transcendental purposes and dwelling in graveyards (Karamustafa, 1994).

Timurid cultural eclecticism and Timur's own unorthodox religious beliefs

According to Manz (1999), Timur's public religious affiliations were largely political. He cultivated powerful Sufi *shayks* who formed part of his inner circle and his primary allegiance was probably to the conservative Naqshbandi order. Timur's own religious practices were Islamic with an admixture of Turco-Mongolian shamanism (Manz, 1999, p. 17) and he "*left an ambiguous record of flights of curiosity into the realms of unorthodox religious beliefs*" (Etheredge, 2011, p. 112). The degree of cultural eclecticism in Timurid Herat may be judged by a court historian's description of the marriage festivities of Timur's son, quoted in Slobin (1976, p. 73).

> *Golden-tongued singers and sweet-sounding musicians played and sang to motives in Persian style, to Arab melodies according to Turkish practice and with Mongol voices, following Chinese laws of singing and Altai meters.*

Conclusions

The most numerous accounts of the use of *A. muscaria* as an intoxicant are drawn from the indigenous peoples of Siberia. However, evidence for contemporary use has been recorded in Spain, Tibet, and Afghanistan. Its association with altered states of consciousness in European folklore (Fericgla, 2001) further suggests, together with linguistic evidence, that the use of *A. muscaria* as an inebriant was, and perhaps still is, much more widely diffused than is generally recognized. *A. muscaria* may have been an important inebriant before the availability of alcohol, which has displaced its use in recent history. As the product of such a cultural crossroads as 15th century Herat, it no longer appears surprising that an image of a psychoactive mushroom should appear as the metaphorical means of ascent in a Timurid representation of the *mi'raj*, the ecstatic heavenly journey of the Prophet. Among the possible sources of this iconography are Pan-Eurasian shamanic practices shared in this case through Turkic contacts with Siberian peoples; the assimilation by Turkic peoples of the practices of Tantric Buddhism which evinces knowledge of *A. muscaria*; or local folk knowledge in Central Asia of the properties of Amanita as evidenced by the archaic practices of the Shutuli elders in the

Hindu Kush.

Abstract

Nineteenth and early 20th century artists portray the Russian witch Baba Yaga with mushrooms, especially with *Amanita muscaria*, the fly agaric. Fairy tales about Baba Yaga, as well as other Slavic folktales, repeatedly contain passing reference to mushrooms, but mushrooms are not integral to story line in Baba Yaga tales. Written documentation for Baba Yaga extends only to late 17th-early 18th centuries, but philological studies and comparative folklore suggest her presence in folk belief considerably before then, plausibly originating from Baltic, Ugric and/or other non-Slavic sources. Linguistic and ethnographic analyses firmly link "baba" and "witch" to various mushrooms in Baltic and Slavic countries. In some tales, Baba Yaga is either the aunt or mother of a certain wizard, whose identity overlaps with another wizard equated with fly agaric. Baba Yaga is also strongly associated with water birds and bird-maidens (*rusalki*). Khanty myth references a water bird assisting creation of Earth from a red-capped mushroom. Baltic myth contains a "Mother of Mushrooms." Pre-Slavic Balkan (Vin&ccaron;a) artifacts include figurines of bird-women, and mushrooms sculpted from rock crystal. Relationships of Balkan, Baltic, Ugric, and other mythic figures to Baba Yaga and to mushrooms are conjectured here and in other literature.

Introduction: early print sources, including illustrations

The witch Baba Yaga, a prominent character in Russian fairy tales, was first well documented in print in the 18th century. The "outstanding Russian poet, scientist, and grammarian" Mikhail Lomonosov referred to Baba Yaga in 1755 in notes in a Russian grammar. In 1780, Vasilii Levshin published a literary fairy tale containing reference to Baba Yaga, and in 1788 there was a comic opera by Dmitry Petrovich Gorchakov in which Baba

Yaga appears with traditional attributes of hut on chicken legs, and mortar and pestle. Details of these and other instances from the late 1700s and early 1800s are summarized by Johns (2004). By 1820, an authentic folktale with Baba Yaga had been published, a version of type tale AT 327C/F (concerning a witch and children). The compiler, Mikhail Makarov, considered Baba Yaga to be "some kind of Slavic deity, known to us from folktales" (Johns, 2004). Early graphic portrayals of Baba Yaga indicate her attributes of association with animals and the mortar and pestle (Figs. 1, 2)

Figure 1. Baba Yaga riding a pig, in a Russian *lubok* (a type of print); possibly a satire on Peter the Great and his wife, or alternatively, a contest between Baba Yaga and a shaman (Farrell 1993) ("early 17th century" in Wikipedia, citing Baldina Ol'ga Dmitrievna, Russkie narodnye kartinki. Moskva, Molodaya gvardiya, 1972). The figure is presented in monochrome by Johns (2004), who stated that it dates from late 17th or early 18th centuries. The object in Baba Yaga's raised hand is a pestle (Farrell, 1993).

Figure 2. From the early 19th century, Baba Yaga (pictured with a devil), is clearly portrayed with her mortar and pestle (Russian National Library). Kabakova (2016) provides multiple archival and literary sources for the figure, of which Fig. 2 is a detail.

Highly enigmatic, and of uncertain affiliation with Baba Yaga, is a putatively Slavic goddess, Tata (or Stata) Baba, 16th century (Fig. 3). According to Thevet (1575) her statue, worshipped as an idol by the Russians, represented a Pietà of some sort (hardly in character with Baba Yaga) and no doubt showing strong Christian influence. Thevet himself never visited Russia.

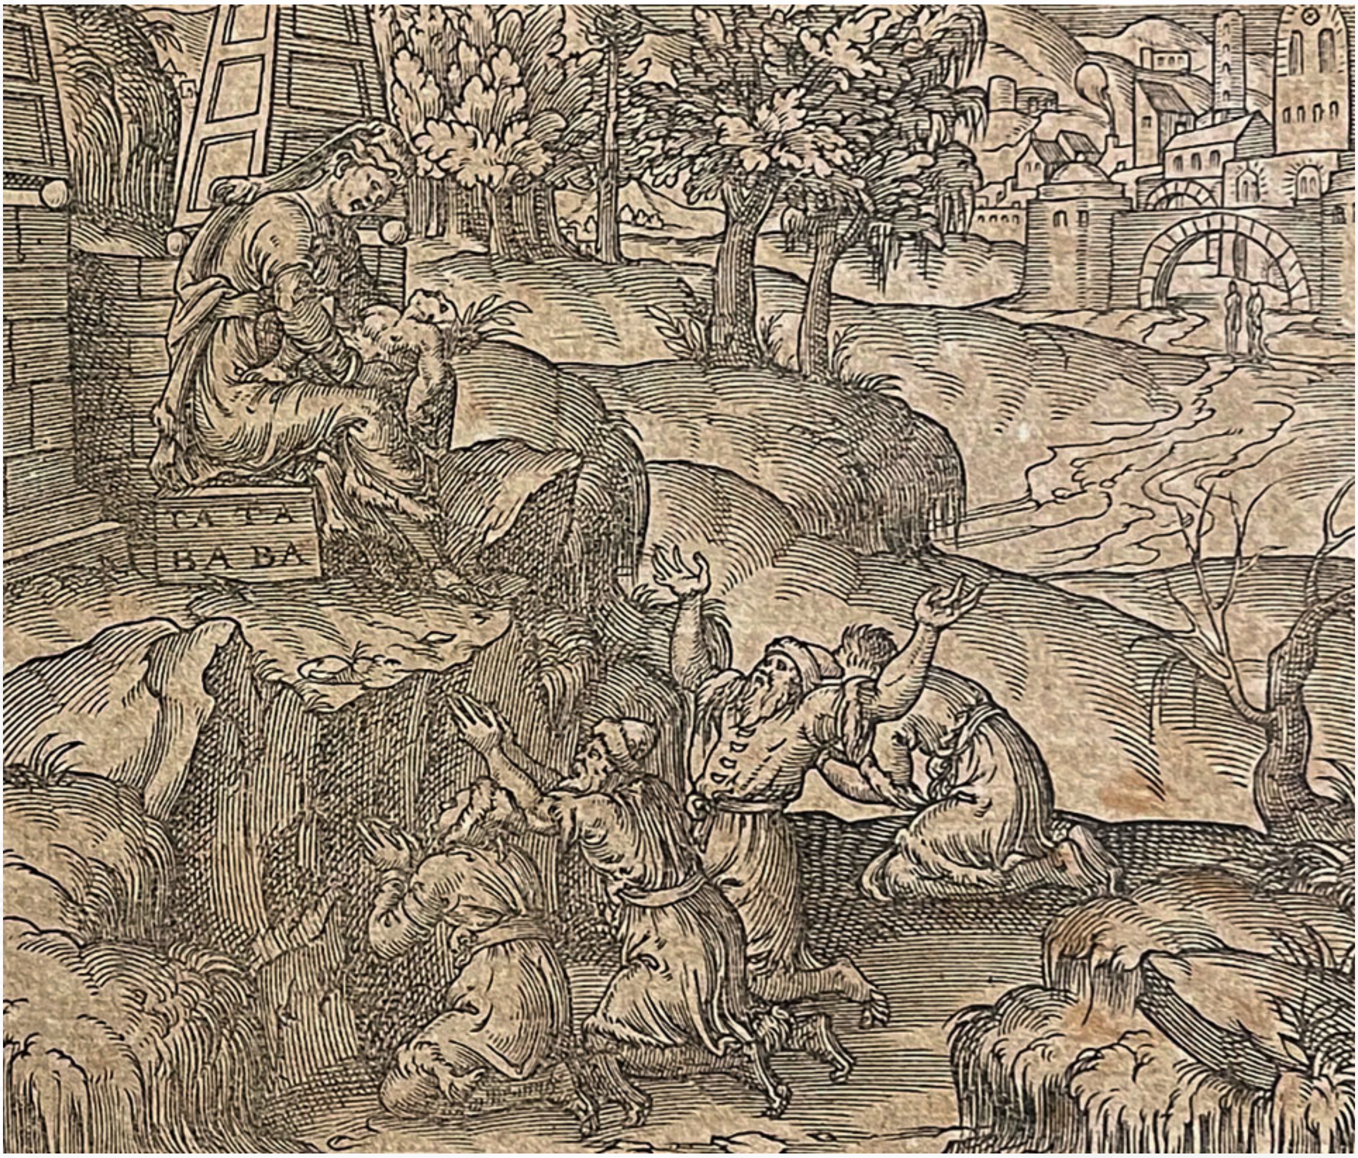

Figure 3. Tata Baba, Muscovy region, by André Thevet, Paris (1575), *Cosmographie Universelle*. "Tata" usually connotes "father" in Slavic, but "stado" connotes "herd" or "flock;" and "baba" connotes an older woman.

Also enigmatic is the relation of Baba Yaga to other ancient Slavic deities. Wood (2015) aims some criticism at Forrester *et al*. (2013) and their sources for being "a little too ready to link Slavic figures such as the Kievan goddess Mokosh [a Mother Earth kind of deity]" to Baba Yaga. However, it seems completely appropriate to inform readers that Baba Yaga shares attributes with some of these deities, e.g., the Baltic Mother of Mushrooms (below), and a female deity analyzed in Propp's (1984) speculations on the Rig-Veda (below).

The famed Aleksandr Afanas'ev (1826-1871), Russia's foremost compiler of Russian folktales, assembled his collections in the early 1850s, most often from prior, unpublished collections. These tales are essentially the equivalent of those assembled by the Brothers Grimm for Germanic tales, and are still readily available in print in English, e.g., Afanas'ev (1945). By the early 1860s, these were appearing in translation in popular periodicals, and contained the familiar (often formulaic) components relevant to Baba Yaga: the hut on chicken legs, the invocation by the protagonist to the hut ("stand with your rear to the forest and your front to us"), Baba Yaga's expression of recognition ("now the flesh of a Russian ... I've smelt with nose and seen with sight"), Baba Yaga's daughters, and her mortar and pestle (Borrow, 1862).

The earliest illustrations I can locate explicitly associating Baba Yaga with mushrooms were painted by Nikolai Nikolaevich Karazin (1820-1908) in 1889 (Fig. 4) and, less explicitly, by Yelena Polenova (1850-1898) in about 1880 (Fig. 5). All the mushrooms are supernaturally large, and certainly appear to belong to Amanita. However, there are reasons, primarily philological but occasionally the contents of certain folktales, to believe that Baba Yaga's associations with mushrooms run much deeper.

Speculation and inference on the antiquity of Baba Yaga

It is not difficult to find conjectures, some more supported than others, on the purported great antiquity of Baba Yaga. The preeminent authority on structure of fairy tales (Märchen, wonder tales) Vladimir Propp (1895-1970), examined a hymn in the Rig-Veda (To the Lady of the Forest, Arany&amacr;ni). Although there is no mention of legs on her hut, the Lady is the Mother of Animals, has a house and/or wagon, and lives in the forest. "We readily recognize Baba Yaga and her hut" (Propp, 1984, posthumous trans.). Among formulaic components such as mentioned above, Propp (2012, posthumous trans.) adds the motif of Baba Yaga as gatekeeper to the boundaries and entrance to the other world. Her dialog with protagonists concerns entry to that world, and "reflects extremely ancient ideas" (Propp, 2012). Marija Gimbutas (1921-1994), widely known for her ideas on the origins of Indo-European peoples, considered Baba Yaba "the ancient Slavic goddess of death and regeneration" (Gimbutas, 1999, posthumous publ.). In her extended thesis on the great antiquity of certain folkways in Eastern Europe, Barber (2013) noted that some folklorists see in Baba Yaga an "ancestral helper along the maternal line." Folktales involving Baba Yaga are integral to Barber's (2013) thesis of folkways (dance, attire, stories) linking mythological female figures to agricultural and human fertility in remote antiquity. Johns (2004) documented the widespread occurrence of "baba" throughout Slavic countries, nearly always with the connotation of "old woman" and derived it from an IndoEuropean root **b(h)&amacr;b(h)-* (* denoting a reconstructed root, i.e., Proto-Indo-European, thus implying considerable antiquity). "The origin and meaning of *Iaga* is [*sic*] far more obscure" (Johns, 2004) and several possibilities are reviewed, including derivations from Baltic and proto-Slavic. Anthropomorphic stone stelae, some associated with Scythian or even earlier times, frequently possess pendant breasts, and are known by several appellations ending in "baba" (Shapiro, 1983).

Another putative link to antiquity is Baba Yaga's affiliation with birds. Her geese, for example, steal children for her (Afanas'ev no. 113, The Geese and Swans), as does the Grey Eagle (Khudiakov no. 53, The Brother) (Forrester *et al.*, 2013). Folktales connecting Baba Yaga with bird maidens were captured by Ivan Bilibin (1876-1942) in a water color (Fig. 6). Such bird maidens were associated with folktales about Baba Yaga and the Firebird (Hubbs, 1988). In Russian folklore, bird maidens are sometimes *rusalki*, having features of archaic goddesses (half female human, half fish, half serpent, etc.) and often displaying malevolent habits. Hubbs (1988) and Barber (2013) considered them very ancient. "They ... echo the hybrid goddesses of Tripol'e [Ukrainian Neolithic]" (Hubbs, 1988). Cheek (2013) stated that "Je&zcaron;ibaba/Baba Yaga" is a more recent phenomenon than *rusalki*, "coming into her own in Slavic tales and Czech tales ... in the 19th century," but as we've seen, Baba Yaga is already well documented in the 18th century. Shapiro (1983) has a view similar to that of Hubbs (1988), and both Shapiro and Johns (2004) note connections of Baba Yaga with serpents as well as with birds. This line of thought is pursued, albeit in an almost chain-of-consciousness fashion, by Richards (2004), where Baba Yaga is linked via a series of motifs combining bird heads atop elongated necks or torsos, to artifacts in the Vin&ccaron;a culture (Transylvania, ca. 5000 BC) (Richards, 2004). It should be added that mushrooms sculpted from rock crystal were recovered in archaeological context from a Vin&ccaron;a site (Gimbutas, 1982). Caveats are essential here, chiefly that it is unproven whether the Vin&ccaron;a culture was, unlike the Slavic, Indo- or even Proto-Indo-European (although it may have had pertinent influence on Proto-Slavic peoples), and there is no way of knowing at present how the mushroom iconography may have been related to the Vin&ccaron;a bird motifs. See however, the connection between water birds and a mushroom at the origin of the world in Baltic myth, below.

Philological, textual and ethnographic evidence on mushrooms

Most pertinent to linking "baba" ("old woman" - "grandmother" - "midwife" - "witch" - or even "dead female ancestor" - etc.) with "mushroom" is the summary of Stankiewicz (1958). "Baba" may even connote a specific kind of "mushroom," e.g., *Boletus edulis* (an eminently edible species) in Polish *babka* (Stankiewicz, 1958). In Slovak, *je&zcaron;ibaba* is the equivalent of Russian Baba *jaga* (*yaga*, *iaga*) (Stankiewicz, 1958). Johns (2004) also reviews multiple interpretations of "baba" and "iaga" and notes the connection to "certain kinds of mushroom." "Baba" in Polish has roughly the same connotations as above in the review of Ostling (2011), who provided an illustration of a baba from ~1685 in which a witchy baba holds a broomstick, and an instance from a witchcraft trial of mushroom powder used to bewitch crops. In 1671, a woman was accused of trying to poison the Tsar's wife with a mushroom, and tortured on suspicion of magic; possession of herbs (a mushroom in this case) was a frequent attribute of those accused of being a witch ("female magician ... midwife ... *baba*") (Ryan, 1998). Dugan (2008a; 2008b; 2011) reviewed ethnographic evidence connecting mushrooms with witches and women, particularly older women, in Europe, especially Slavic and Baltic countries.

This connection may be responsible for elements in Edgeworth (1869), a work of fiction wherein two gentlemen traveling in Lithuania are accosted by an elderly "sorceress" and "witch," who conjures a serpent from a basket of mushrooms while invoking the name of a putatively ancient Slavic deity. Edgeworth (1869) was an abridgement of a work of the same date by Prosper Mérimée (1803-1870), but the story was not fully translated from French into English until Mérimée (1905), with an illustration of the witch, her mushrooms and the serpent (Fig. 7). Whether this episode reflects genuine folklore or is more appropriately treated as "fakelore" is conjectural. Elements of purported Slavic paganism were here being combined in popular literature with mushrooms, serpents and witchcraft, although Baba Yaga was not directly referenced. One mushroom in the witch's basket elicited comment from the gentlemen, but it was *Agaricus necator* (*Lactarius necator*, considered inedible in western countries but preserved in salt in Eastern Europe), not an Amanita. That Slavic peoples consumed fungi avoided by peoples to the west was the opinion of Lyall (1823), who provided an extensive synopsis on mycophagy in Russia of the early 19th century and earlier. Lyall (1823) made no reference to witches with regard to mushrooms, but noted the special role of Russian women in collecting fungi.

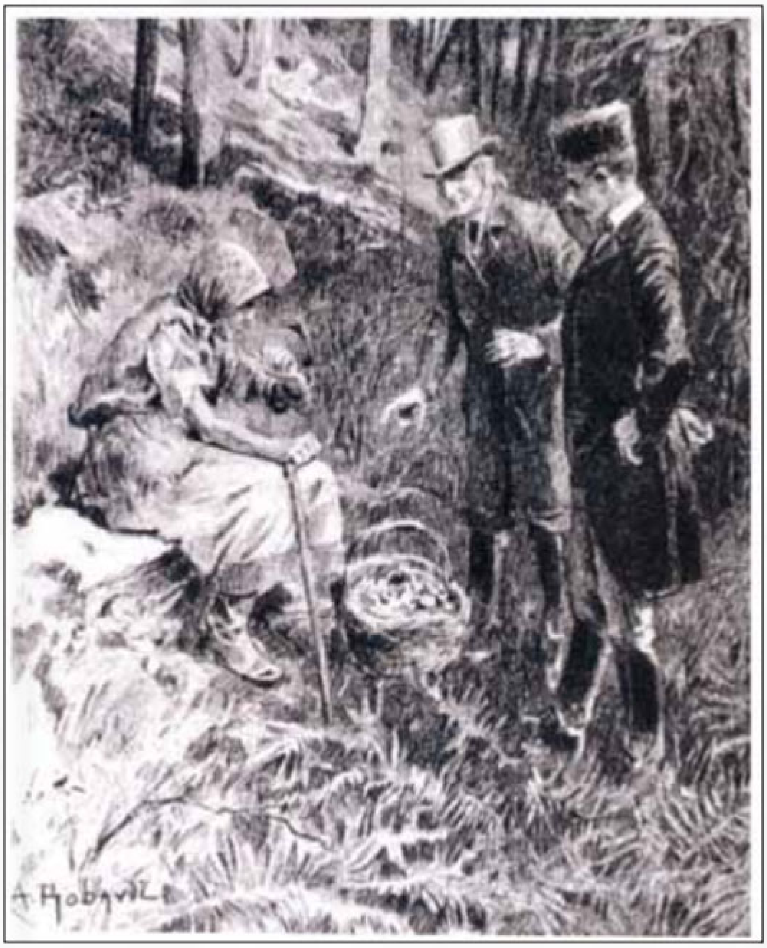

Figure 7. The witch in Mérimée (1905), an English translation from the French of 1869. A pagan Slavic god is invoked; a snake conjured from a basket of mushrooms coils around the witch's left arm. Artist: A. Robaudi.

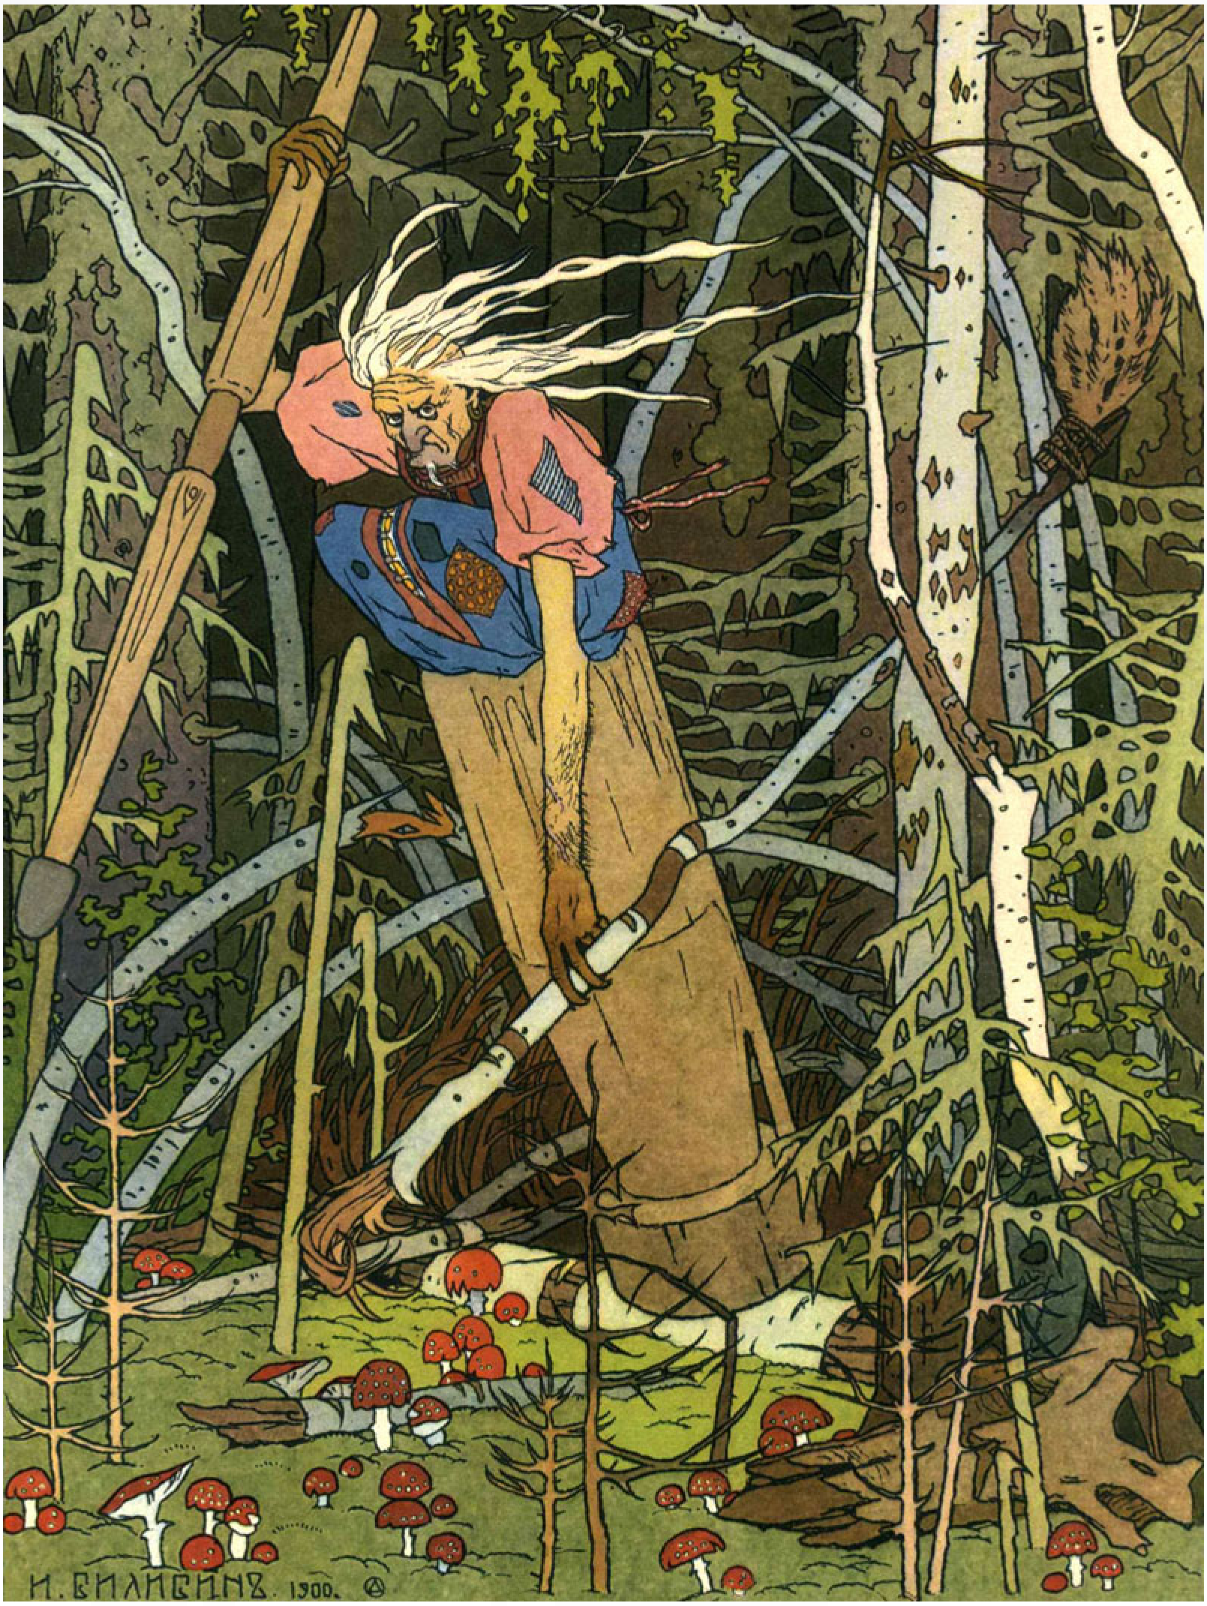
The general semiotic significance of mushrooms in myth was reviewed by Toporov (1985), with occasional reference to usages linking mushrooms to thunder and/or lightning and deities personifying them, e.g., Perun the Slavic god of thunder. Johns (2004) reviewed, somewhat skeptically, previous opinion linking Baba Yaga to storm clouds. More prosaically, a Russian forest spirit (and sometimes associate of Baba Yaga), the *leshii*, would assume the likeness of a mushroom or alter the appearance of mushrooms with a whip; in the north, such spirits were associated with storm winds (Ivanits, 1989). According to Deteli&cacute; (1998), the Slovenes had a ritual of rolling on the ground at "first thunder" (of the season?) to promote an abundant harvest of white mushrooms. The first mushrooms found during a mushroom harvest ("first fruits") might be offered as a sacrifice to a forest spirit, albeit with addition of Christian prayer (Wenska, 2015). Notably, the spirit was identified with Veles, a chthonic and aquatic deity distinct from Perun (Wenska, 2015).

Mushrooms were a component of Baltic and Ugric religion. There was a "Mother of Mushrooms" (S&ecaron;ņu m&amacr;te) in Baltic religion. Opinions are divided on whether such "mothers" or goddesses in Baltic religion indicate influence of the Christian Virgin Mary (Ankrava, 2013; Biezais and Ankrava, 2005). There is a reference to Earth originating as a "red-cropped" [sic - "red-capped"?] mushroom in myths of the Khanty, an indigenous Ugric people, near Ob River, Russia. This origin, subsequent to the Deluge, was wrought by a bird, Luli (a small loon) (Deviatkina, 2011), although there are different versions, less specific about the bird ("water bird" or "diving bird" or specifying other birds like sandpiper, swan or grebe) and omitting the mushroom (Deviatkina, 2011; Limerov, 2005).



И. БИЛИБИНЪ. 1900.

Figure 8. Baba Yaga by Ivan Bilibin (1902), with fly agarics in foreground (Wikimedia). Bilibin and Zworykin (Fig. 9) were influenced by Yelena Polenova's illustrations of mushrooms (see Dugan, 2016).

Hubbs (1988) related a folksong, a stanza of which goes, "Where old women go mushrooms grow, Oi Liuli [Lada]." Lada is a name commonly occurring in planting or harvest songs in Russia, and "has been linked to a Latvian goddess, as well as to the Golden *baba* of the Ugrians" (Hubbs, 1988, with commentary on various possible origins for Lada). "Lada" is also linked to other "baba" names, or more specifically to a close analog "Boda" in a Polish document of about 1550 (Marjani&cacute;, 2003, with commentary on the antiquity of "baba" names for ancient Serbian and Croatian female deities). Baba Yaga is not explicitly linked to the Golden Baba, but Johns (2004) noted the possibility of a non-Russian (and probably northern) origin for Baba Yaga, based on the formulaic nature of her response to a Russian visitor, i.e., her statement that she smells a Russian, and that it has been a long time since a Russian has come to her. Johns (2004) lists water birds (including pelicans, swans, etc.) associated with Baba Yaga. Goscilo (2013) noted that the legs on Baba Yaga's hut are congruent with the "legs" formed by bases of trees used as platforms for storage huts by indigenous peoples of the Russian north. Hatto (2017) has an analogous opinion on the resemblance of the Khanty "Idol-Hut" to Baba Yaga's dwelling, and describes several Khanty practices involving fly agaric (*Amanita muscaria*). So it is plausible, but scarcely certain, that the Slavic Baba Yaga was derived from Baltic and/or Ugric mythologies, whose female divinities had connections to mushrooms and birds. According to famed founder of ethnomycology R. Gordon Wasson (1898-1986), the wise women (*javas asszony*) of Hungarian tradition used fly agaric for love philtres (Wasson, 1968). Hungarian (Magyar) is a branch of Ugric, this relation explaining why the use of fly agaric, documented in Ugric lore, persisted in Hungarian folkways (Czigány, 1980). Outside these traditions, it is recorded that Swedish witches of the 17th century made salves of mushrooms ("*röd flugsvamp-amanita muscaria*") and stored them in horns, also used for storing salves of hemp, opium and henbane (Jordon, 2012, citing a source in Swedish).

However, individual folktales in which Baba Yaga herself has direct and explicit connections with mushrooms are hard to find. Goscilo (2013) stated that mushrooms are "never mentioned in Russian fairy tales," but this is an exaggeration. It certainly does not apply to all Russian folktales, e.g., The War of The Mushrooms, a well-known folk poem (Dugan, 2016), but not directly pertinent to Baba Yaga. In Russian fairy tales *per se*, (Märchen, wonder tales), mushrooms appear, but usually incidentally, e.g., "One day the man went into the woods to get mushrooms" (Baba Yaga and the Runt, Afanas'ev no. 105, in Forrester *et al*. 2013). Similarly, in Ivanko the Bear's Son (Afanas'ev, 1945), "One day the wife went to the forest for mushrooms ..." This usage, in a culture in which mushroom hunting is a common pastime, is equivalent to saying, "Once upon a time." In another Afanas'ev collection (Haney, 2014) we likewise have a tale with Baba Yaga's daughters (AT 301, involving stolen princesses), in which characters search for berries or mushrooms. These instances use mushroom hunting to situate the tale, but mushrooms themselves are not integral to the plot. Mushrooms comprise part of a story line in The Fool and the Birch Tree (Afanas'ev v., no. 53, Ralston 1880), where the clever brothers lie to an avaricious cleric that they have no money, only mushrooms, but the foolish brother speaks the truth; a series of events ensue, but none pertinent to Baba Yaga. Mushrooms are also integral to plot in The Milk of the Beasts (Afanas'ev 203) wherein the fool (our hero) collects mushrooms, and then discovers the hideout of the robbers. He defeats them, and fills his mushroom basket with their gold, which he gives to his sister (Haney, 2015), but again Baba Yaga is not involved.

Very intriguingly, in some Russian tales there is a villainous wizard, Mukhomor, sometimes equated with the equally bad Koshchei the Deathless (The Enchanted Tsardom, in Haney, 2013). Mukhomor "means 'Poison Mushroom' (Fly-agaric)" (Haney, 2013), and indeed the "moucho-more, a deleterious species of mushroom" was early recorded as comprising "entertainments" of Siberian tribesmen (Von Kotzebue, 1830), an obvious allusion to use of fly agaric for intoxication (e.g., Wasson, 1968). Koshchei and Baba Yaga can appear in the same tale. Baba Yaga is either his aunt or his mother (Shapiro, 1983), and the association between Koshchei, Baba Yaga and fly agarics persists in contemporary Russian grade school games (Yamin-Pasternak, personal communication). I have not seen the name "Mukhomor" directly linked to Baba Yaga in older folktales. But in some contemporary Russian tales and theater productions, there occurs the name "Mukhomorovna" or "Yaga Mukhomorovna," e.g., Baba Yaga's patronymic, "daughter of Mukhomor" (Yamin-Pasternak, personal communication). A distinguished scholar of Russian literature and folklore, W.R.S. Ralston (1828-1889), provided summaries of the relation between Baba Yaga, Koshchei and their roles in Russian and Slavonic folklore, often with reference to the perspectives of Afanas'ev (Ralston, 1872).

Soidla and Shapiro (1997) cited Propp (1986, posthumous, in Russian, pp. 66-67) for Baba Yaga treating visitors to "magical foods or drinks intended for the dead and not for the living." The authors go on to state, "Of the magical foods, mushrooms seem to be most common, and some Baba-Yaga tales contain references to mushrooms in several contexts. Illustrations for these tales (although certainly done much later than the tales themselves) often depict Baba-Yaga surrounded by red fly agaric and other mushrooms." It is unclear on the basis of Soidla and Shapiro (1997) if the use of mushrooms in this manner, e.g., as a magical food, is contained in Propp (1986) or is an inference by the authors.[1] Their primary example of mushrooms in a fairy tale consists of "Baba Yaga sets off into the woods to gather mushrooms and parsley for the stew and finds a hedgehog sitting on top of a big mushroom and eating a mushroom." The hedgehog becomes a boy who is the protagonist of the tale. This tale is unsurprisingly mentioned in works devoted to mushrooms, e.g., Marley (2010), citing Vilenskaya (n.d.).[2] The theme of mushrooms as magical foods dispensed by Baba Yaga is also addressed by Ivanova (2013), but specific citations for this occurrence are not provided so it is unclear whether or not this use of mushrooms is Ivanova's inference. Propp (1968) mentions specific examples of food or beverages acting as magic agents, but mushrooms are not specified.

Multiple illustrations by Bilibin for folktales involving Baga Yaga included mushrooms, especially fly agaric (*Amanita muscaria*) (Fig. 8). Similar illustrations, numerous and widely known, were produced by contemporaries, e.g. Boris Zworykin (1872-1942, Fig. 9).[3] Over decades, inclusion of fly agaric in illustrations of Baba Yaga tales became standard, such as those by Peter Koshkin for Baba Yaga and Vasilisa the Beautiful (pp 90-91, in Warner, 1985).

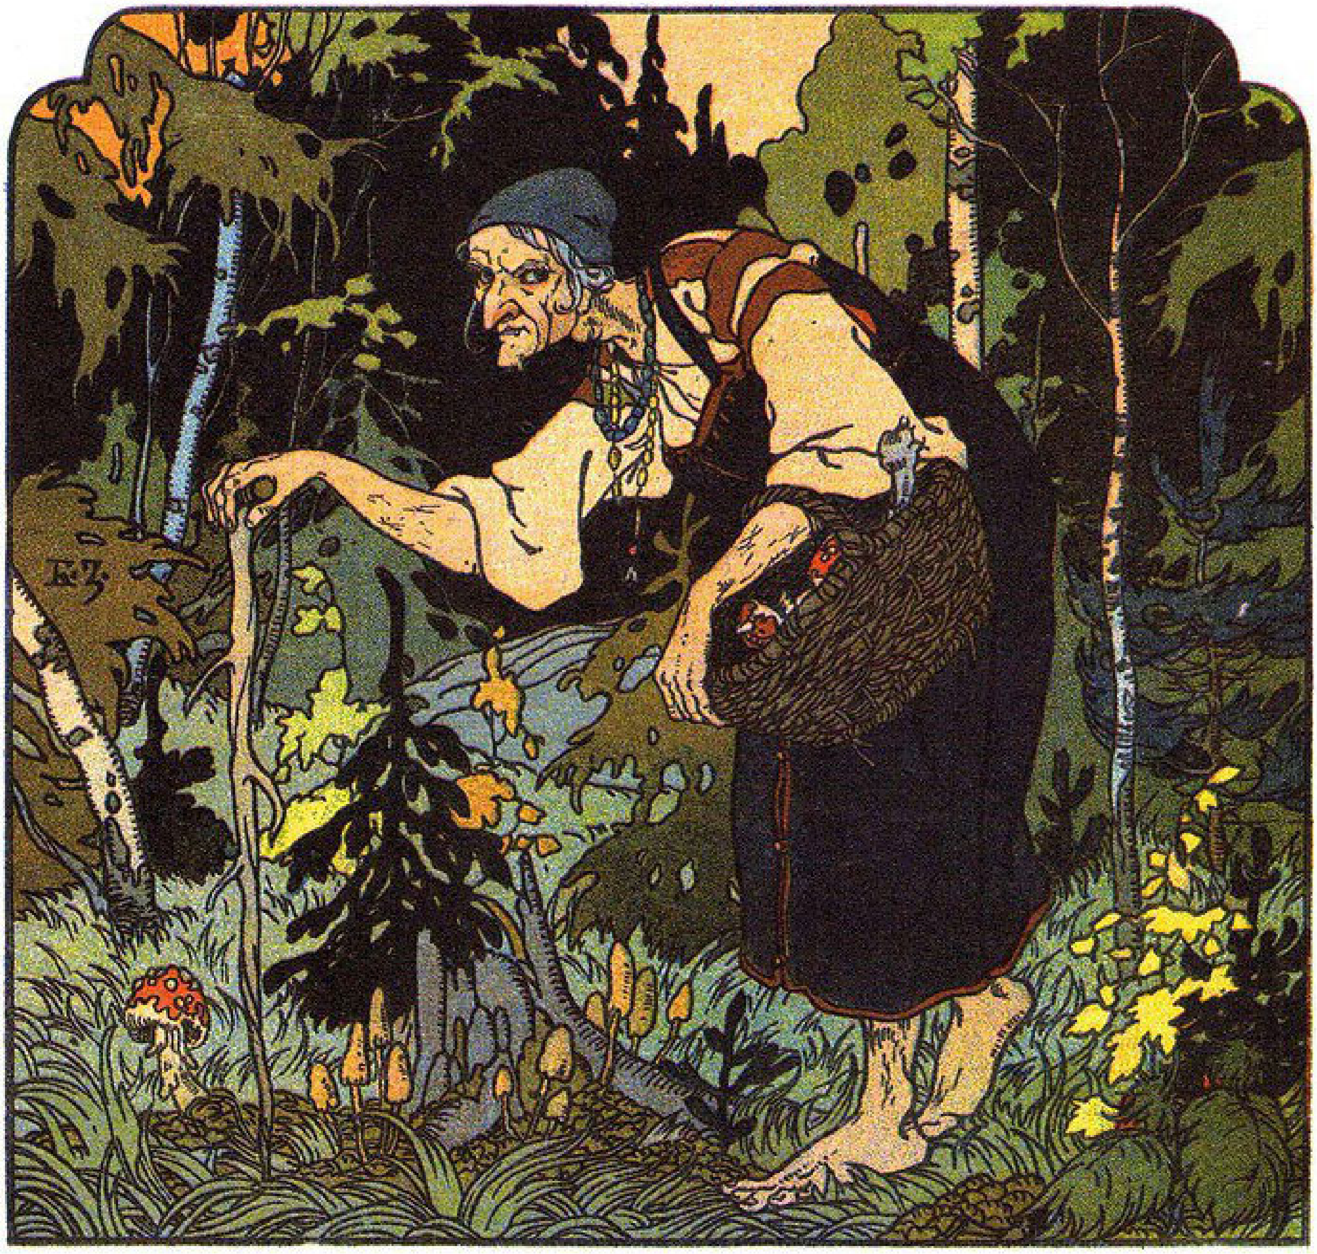


Figure 9. Boris Zworykin's Baba Yaga (1917, in V.A. Smirnov, The Witch and the Strawberries) with fly agaric in lower left. Zworykin has been called "the shadow that followed Bilibin" (forum.artinvestment.ru) but their works were largely contemporaneous.

That the fly agaric was pictorially inserted into Baba Yaga tales well prior to the more recent enthusiasm of mycophiles for Wasson's (1968) thesis on soma is demonstrated not only by Bilibin's artwork and that of contemporaries, e.g., Zworykin and Viktor Vasnetsov, 1848-1926 (Fig. 10), but is suggested by the *Amanita*-like mushroom in Karazin (1889). Prior to Karazin (1889), Yelena Polenova painted "Masha and Vanya" (~1880) with fly agarics (http://schwarzze.livejournal. com/248633.html). In this tale (number 113 in the Afanas'ev collections), Baba Yaga's swan-geese capture Vanya, who must be rescued by his sister, but in the painting itself (Fig. 5) only the siblings are shown. Unsurprisingly, Wasson enthusiasts (see *In Wasson's footsteps* (sort of), Dugan, 2011) have suggested that *A. muscaria* be added to Baba Yaga's accoutrements, e.g., Dunn (1973).

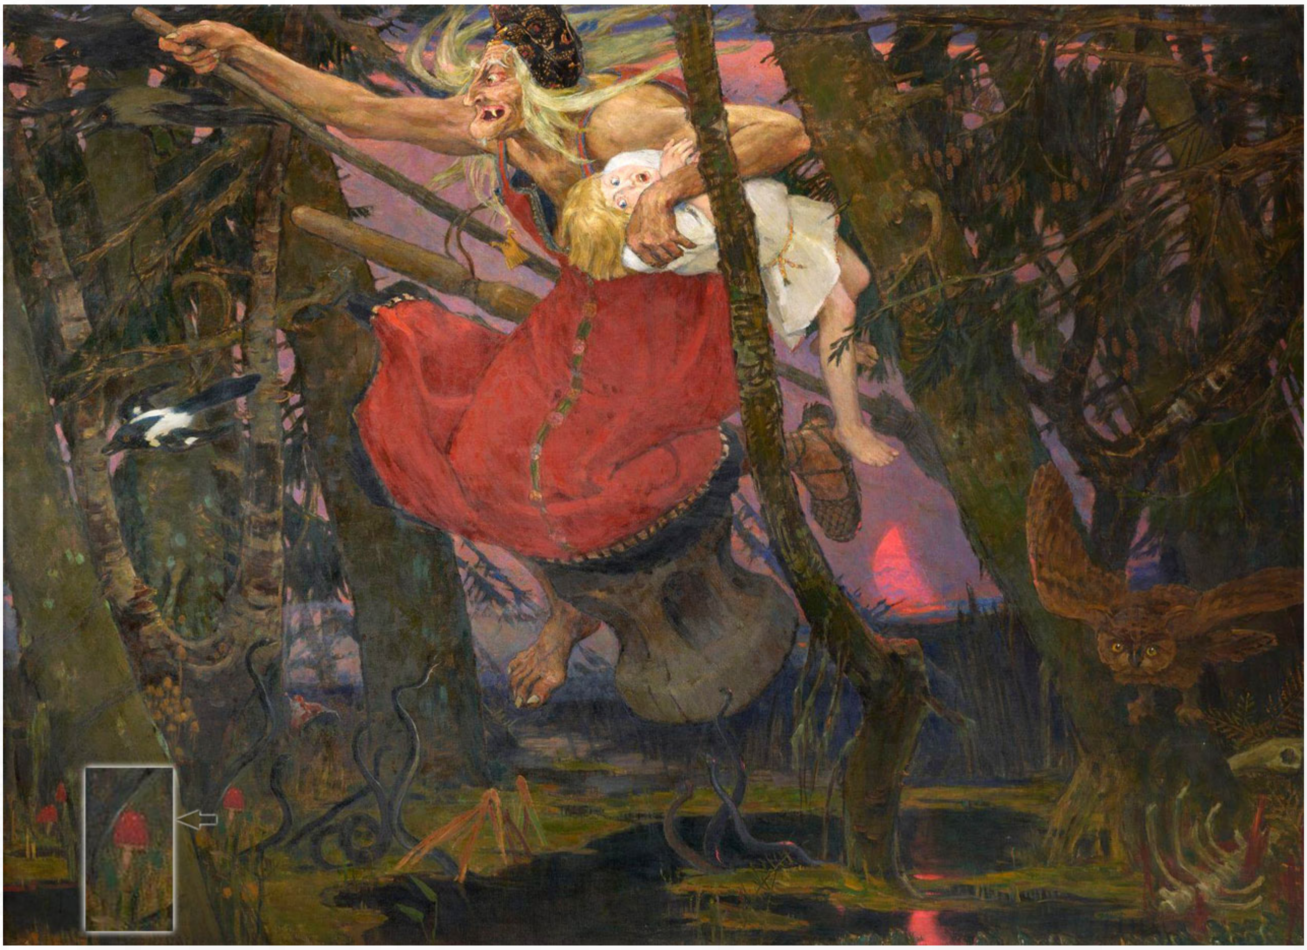

Figure 10. Baba Yaga, by Viktor Vasnetsov (1917, Wikimedia), emphasizing Baba Yaga's reputation of kidnapping children for her dinner. Inconspicuous fly agarics are visible in the lower left corner (arrow, and insert).

Items manufactured in the Russian folk tradition (or at least imitating that tradition) very frequently include images of Baba Yaga in association with the fly agaric. Lacquer boxes in particular (Fig. 11) can be readily located in online images, often on pinterest.com or other sites, and usually feature the hut on chicken legs, Baba Yaga, and a mortar (but sometimes with a broomstick substituted for the pestle and with Westernized accoutrements, e.g., black cats, cauldrons, etc.). Google Shopping offers an assortment of Russian lacquer ware on which Baba Yaga and fly agaric mushrooms are often conspicuous. Baga Yaga items comprising stained glass, coasters, lacquer, tapestries and other items on esty.com also include *Amanita* motifs. Bilibin prints, many predictably including little red-capped mushrooms with white dots, are offered on ebay.com. Fly agarics ornament Baba Yaga books and dolls offered by amazon.com. From zazzle.com you can get your Vasilisa the Beautiful coffee mug, and other mugs with similar Baba Yaga themes, with or without fly agarics.

The box showing Baba Yaga dropping an *Amanita* into a cauldron (top middle), is captioned by Goscilo (2013) as demonstrating "the Russian handicraft industry's profit-driven catering to Western traditions and tastes.

Discussion and conclusions

Philological and ethnographic evidence strongly supports the notion that Baba Yaga has been present in Russian folk tradition much longer than written documentation alone attests. Persons well acquainted with this tradition repeatedly use the word "ancient" but usually without quantification. It is probably safe to infer that Baba Yaga was already established in folklore during medieval times. If Propp (1984) was correct, we might even surmise that the Lady of the Forest and Baba Yaga had a common origin in distant Indo-European or even ProtoIndo-European times. However, in another comparison (that of the princess Elena the Wise with the ancient Greek Demeter), Propp (1984) was careful to note, "Even though we compare Demeter and the princess, it does not mean our princess is a direct descendent of Demeter. It only means that features of the goddess of agriculture are characteristic of the princess." This cautious attitude might equally apply to the brilliantly intuitive but highly speculative work of Barber (2013). Motifs may be shuffled between tales, and tales between cultures, and as Propp (1968) emphasized, different folk characters may be exchanged between tales, and the same function within tales might be fulfilled by different characters.

Mushrooms have played a prominent role in Russian cultural life, seemingly for centuries. They are so embedded, that to say a given character went to gather mushrooms is a standard introductory motif for a folktale, including some tales about Baba Yaga. In Russian fairy tales, it is therefore not surprising that mushrooms are occasionally in the background and have become a standard fixture of Russian fairy tale illustration. It seems they are usually more emblematic of setting than of function or plot ("morphology" *sensu* Propp, 1968). But there are hints at deeper roles: "Mother of Mushrooms" in Baltic lore and a plausible connection of the Ugric "Golden *baba*" with mushrooms; the fairy tale wizard named "Poison Mushroom;" and philological connections between "baba" and mushrooms. One wonders where Karazin made the connection between Baba Yaga and Amanita, as the giant *Amanita*-like mushroom in Karazin (1889) was painted when Bilibin was only thirteen. Were Karazin, Zworykin, Bilibin and their contemporaries drawing from a shared folk tradition, or merely echoing prior artistic approaches, e.g., Polenova? Antedating Polenova's painting, Modest

Mussorgsky's composition, Pictures at an Exhibition (1874) incorporated a theme, "The Hut on Chicken Legs" after a painting by Mussorgsky's friend, the painter Victor Hartmann (1834-1873). Hartmann himself once shocked his contemporaries by going to a costume ball dressed as Baba Yaga (www.stmoroky.com). Mussorgsky's "Gathering Mushrooms" (1867) has lyrics in which the woman collecting these fungi considers using them as poison on her husband. These established facts do *not* indicate that either Mussorgsky or Hartmann directly connected Baba Yaga with mushrooms, but the possibility is implied. It may be mere coincidence (or not) that the conductor Sir Henry Wood (1869-1944) later added mushroom bells (mushroom-shaped percussive instruments) to the orchestration for "The Hut on Chicken Legs" (www.musicweb-international.com).

Especially intriguing is the possibility that Baba Yaga and her hut are derived in part from ancient Baltic and Ugric beliefs, including the myth of a red-capped mushroom and water birds. Going even farther back in time, were the enigmatic Vin&ccaron;a mushroom sculptures in any way related to the Vin&ccaron;a bird-women figurines, and did these remote motifs foreshadow folk concepts of Baba Yaga?

These tantalizing conjectures entice us to explore the depths underlying contemporary fairy tale convention and ornament. Some persons who have delved into the impacts of *Amanita* on folk belief have made startling (specious?) claims, including that cultic beliefs about *Amanita muscaria* underpin Mediterranean and European history (e.g., Allegro, 1970; Ruck *et al*., 2011). Others claim to have unlocked the keys to eternity by channeling conversations with ancient Egyptian *Amanita*-users (Puharich, 1959, with cameo appearances by Aldous Huxley and Gordon Wasson). With more restricted ambition, we might try unlocking the shamanic roots of European fairy tales, for which Ruck *et al*. (2007) made valiant efforts, but pertaining to Baba Yaga (and in spite of a wonderful picture of her on the jacket, with fly agarics!), they uncovered little not addressed here.[4] Ruck *et al*. (2007; 2011) followed other scholars (Allegro, 1970; Wasson, 1968; and many others, less well-known) in surmising that the fly agaric had foundational impacts on world history, myth and religion, and in constructing their own highly detailed account. Readers are encouraged to explore such accounts, but urged to keep their skepticism intact.

Proceeding with caution, we might remind ourselves that written source materials on Baba Yaga date only from late 17th-early 18th century, and I have found pictorial sources relating Baba Yaga to mushrooms only from late 19*th* century onwards. Openly practiced paganism existed in Eastern Europe well into the 10*th* century, and Baltic, Finno-Ugric and Prussian paganism was suppressed by the Teutonic Knights only in the 13*th* century (Barford, 2001), but written sources from those times describing pagan folklore are virtually nonexistent. Pagan lore usually must be inferred from Church documents hostile to pagan belief (Filotas, 2005). Although there is a literature on pagan influences on festivals, holidays and the like, most derives from Western Europe (e.g., Dugan, 2015), and gleanings on Baba Yaga and Eastern European shamanism are slim (Johns, 2004). But that pre-Christian beliefs long lingered below the surface was evident to persons familiar with Pre-Revolutionary Russia: "The old pagan religion, too, is a secret institution ... the wood-sprites have their abode; whilst the lakes, rivers, and waterfalls abound in water-sprites, of whom the Roosalka are the most dangerous ... The cult of the wood-sprite obtains mostly in the forest region ... whilst the water cult (the worship of water-sprites) prevails among the thousands of fishermen, raftsmen, boatmen, and sailors of the mighty rivers and lakes" (Steveni, 1913). A pagan storm deity was by then "the Tsar of the winds, who ... is also very common" (Steveni, 1913). After providing concise accounts of several offerings and sacrifices to the various sprites by both Russians and Finnish tribes along the upper Volga, Steveni (who spent more than 10 years in Russia), mentions the "wise woman" in northern Russian villages, "who effects cures by spells and incantations and the use of herbs." Here we are not so far from the world of Baba Yaga. But although belief in witches is specified, Baba Yaga herself is not mentioned and mushrooms are only referenced as a common food in Steveni (1913). Use of herbs and roots, as well as potions and incantations, were frequently mentioned in Russian witchcraft trials of earlier times (Zguta, 1977). References to fly agaric in Jordon (2012), pertaining to Swedish witches, and in Czigány (1980), pertaining to "wise women" in Hungary, are especially engaging, as they relate use of fly agaric in the traditions of northern and central Europe, respectively, as opposed to the shamanic traditions of Siberia. Is the presence of the wizard Mukhomor ("Fly-agaric") in Russian fairy tales an indication of a bridge between Siberian and west/ central European traditions? Might Baba Yaga also be found on this bridge?

At present, rather than create our own mythologies, it is best to admit the paucity of sources and the limits of reasonable conjecture. The Baba Yaga of fairy tales is likely the result of anastomosis between numerous strands, some glimpsed by us only faintly and fleetingly. It seems unlikely that any single strand comprised a "true" Baba Yaga of remote antiquity, but each may have contributed to her eventual identity, including her association with mushrooms.

1. Taras Nazarov and Sveta Yamin-Pasternak, both fluent in Russian, read pages 66-67 of the 1986 edition and confirmed this result: mushrooms are not mentioned by Propp (1986) on these pages.
2. Vilenskaya (n.d.) cited Small (1966), as did Ruck *et al*. (2007) for this story of a hedgehog and mushrooms. Her phrasing, seemingly straight from Small (1966), is word-for-word the same as that of Soidla and Shapiro (1997). Small's (1966) tale was "drawn together into one story" from "such sources as" (Small lists several 20th century fairy tale compilations). Small (1966) is an engaging tale written for children, but of indefinite (or mixed) provenance.
3. Bilibin was in Germany in 1898 and 1900, where other artists portrayed witches with mushrooms. Heinrich Vogeler's *Die Hexe mit Eule* (1895) includes *Amanita* mushrooms. Alexander Zick (1845-1907) portrayed the witch in *Hänsel et Gretel avec la sorcière* (date unknown) with red-capped mushrooms. German artists Paul Meyerheim (1843-1915) and Hermann Vogel (1856-1918) showed mushrooms with witches or other fairy tale characters in the 1890s. In England, Edgar Bundy's A Witch (1896) contained fly agarics. H.J. Ford's *The Witch-Maiden* (Yellow Fairy Book, 1894) has a fly agaric. Such examples could be multiplied and after 1900 were abundant.
4. Ruck *et al*. (2007) cite Propp (1986) in support of their statement on Baba Yaga and "the gateway to another world ... through purveyance of magical food and drink, most often mushrooms, commonly depicted, *at least in late illustrations*, as fly agarics" (emphasis added). As indicated in footnote 1, I can find no evidence that Propp (1986) actually mentioned mushrooms in this regard. In their footnote 5, referencing Propp (1986), Ruck *et al*. (2007) also cite Vilenskaya (n.d.), who like Soidla and Shapiro (1997), specifically referred to Propp (1986, pp. 66-67) in support of mushrooms being magical food. Ivanova (2013) wrote that mushrooms were "supposedly" the food leading to the other world, but directly cited no specific source. One might tentatively conclude that this persistent citing of Propp (1986, pp 66-67), who did not actually specify mushrooms on those pages, and of Small (1966), whose tale of Baba Yaga, a hedgehog and mushrooms was a late synthesis (see footnote 2), have lent too much credence to the idea that Baba Yaga was intimately connected with mushrooms in authentic, transcribed folktales. Whether or not she was associated with mushrooms in other folkways, including with the wizard Mukhomor (fly agaric) is a different matter.

Abstract

Little has been written on the financial support behind Timothy Leary's unorthodox research into mind-altering drugs like LSD and psilocybin and his subsequent psychedelic movement. Indeed several individuals and organizations helped the psychedelic cause by directly funding Leary's ventures, offering legal and logistic assistance, and organizing fund-raising campaigns. I argue that classic philanthropic attitudes and wealthy patrons played a major supporting role for Leary's psychedelic movement in the first part of the decade and that the changes in Leary's research objectives and his transition from academic to LSD guru were accompanied by changes in the patterns of support that occurred throughout the 1960s. This paper also connects Leary's legal troubles in the second part of the decade with the rise of the movement to legalize cannabis and points to historical continuity by looking at contemporary endeavors to fund psychedelic research.

Keywords: activism, cannabis, LSD and psychedelics, philanthropy, Timothy Leary

1. Introduction

The 1960s are remembered as a decade when Americans experimented with a wide-range of illicit drugs. In particular, psychedelics like LSD, mescaline, psilocybin, peyote, DMT, and cannabis,1 emerged as a new category of mind-altering substances that could shatter the senses, trigger other-worldly visions, distort notions of time and space, and lead to moments of deep introspection. As these drugs grew in popularity, a movement made up of intellectuals, artists, and religious figures reasoned that psychedelics had the power to radically transform humanity and promoted them accordingly: if everyone altered their brain chemistries with these drugs, global peace, love, and understanding would naturally ensue (Conners, 2010; Elcock, 2013, 2015; Greenfield, 2006; Higgs, 2006; Lee & Shlain, 1985; Stevens, 1988).

Harvard psychologist Timothy Leary was one of many to experiment and to become enamored with psilocybin mushrooms and LSD. As an academic, he was initially keen to study the effects of these drugs on human personality but he came to realize that they were too important to remain in the academy and that they should be promoted on a much larger scale. His research became increasingly idiosyncratic and Harvard and Leary were forced to part in 1963 following reports of drug use on campus and of unethical drug research on human subjects. After this first public controversy, authorities kept close tabs on him and in December 1965 he was arrested at the Texas-Mexico border for cannabis possession. Scrambling for support, he renewed his efforts to promote these drugs in a more aggressive way by explicitly framing the psychedelic experience as inherently religious to invoke his rights as a practicing Hindu (Lander, 2014), but after two more drug busts justice finally sidelined the notorious proselytizer in 1970.

While the jury is still out on Leary and his legacy, this canonical narrative says little about the role of the people who were taken to his persona and who were so impressed by his psychedelic undertakings that they decided to help him through financial contributions and logistic assistance. Based on publications in magazines and newspapers, letters, memoirs, and personal communications, this paper argues that Leary's movement[2] was helped by typical philanthropic attitudes drawing from a long tradition in American life in spite of the controversies surrounding LSD and its association with the counter-culture in the second part of the 1960s. Americans from various backgrounds reasoned that if the psychedelic experience was such a great asset for humanity, then they should become the protectors and the benefactors of the psychedelic movement. And when the controversial Leary ran into trouble with the law, many stepped in to offer their support and donated to a fund created for his legal expenses.

By examining the role of Leary's supporters this paper seeks to offer an alternative to the two dominant takes on the history of the psychedelic movement (in contrast with the general historical scholarship on the history of LSD and psychedelics, which has been growing exponentially over last few years through increasingly varied approaches and geographical focuses (Aronov, 2019; Dawson, 2018; Hartgosohn, 2020; S. Marks, 2015; Oram, 2018; Richert & Dyck, 2020)). Indeed several historians and commentators have dismissed Leary's movement as an embarrassment and only given it surface treatment in their analyses by zeroing on the controversies surrounding that history, such as the psychedelic movement's extreme and provocative rhetoric.[3] In particular, they have condemned Leary for his reckless promotion of psychedelic drugs and in doing so, they have downplayed his well-documented claims of enlightenment through psychedelic experimentation.

By contrast a revisionist school, partly through the lens of spirituality, has based its interpretations on the premise that psychedelics had the power to induce a complex spiritual experience, which became the cornerstone of Leary's promotion of these drugs (Fuller, 2000; Kent, 2001; Lander, 2011, 2014; Shipley, 2015).[4] While this side of the scholarship has paid a lot more attention to claims of drug-induced enlightenment, I focus instead on the behind-the-scenes history of the psychedelic movement, rather than its well-publicized and sensational aspects, to move away from Leary at the center-stage of this narrative and examine the more discreet and influential players who made this movement possible.

This paper begins with a brief contextualization by looking at psychedelic funding in other research groups and goes on to illustrate the main argument by identifying several key events and periods that were accompanied by changes in the patterns of support for Leary's work. First, his discovery of psilocybin in 1960 and his fascination for the drug led him to share his enthusiasm with several influential New Yorkers, including Beat poet Allen Ginsberg who convinced him that it was an important asset for humanity and that it should be enjoyed by all. In turn, this spurred Leary to successfully court the support of the New York upper class to sponsor his research by channeling funds to Harvard. At the time he was not the controversial and polarizing figure he became in the second part of the 1960s and his research was thought to be a legitimate way of contributing to the "well-being of mankind" (Zunz, 2012a) that deserved adequate support.

Second Leary's first contact with LSD in 1961 made an even greater impression on him and led him to believe that reality was merely a cultural construct. As a result his research became increasingly idiosyncratic and by the time Harvard had moved to oust him and his closest lieutenant Richard Alpert (who subsequently dismissed drugs and became Baba Ram Dass) in 1963 Leary was already setting his sights on experimenting with psychedelics outside the confines of academia. During that period most of the classic patronage dried up but two millionaires and heirs to the Mellon family continued to help Leary and his group by allowing them to settle on their spacious mansion in Millbrook, New York. Their continuing support may come as a surprise given the radicalization of his thought, but then in the larger social history of the 1960s even the radical turn of the civil rights movement in the second part of the decade did not put an end to its philanthropic support (Zunz, 2012a, p. 201).

Finally, Leary and his associates carried on with their freewheeling psychedelic explorations but his 1965 arrest for cannabis possession was a watershed moment that gave him added media coverage and contributed to a major shift away from classic philanthropy. Leary finished discarding what was left of his academic career, appointed himself the "High Priest" of LSD, and from then on systematically touted the drug as a Godsend and a cure-for-all. Meanwhile what had begun as behavioral research into psychedelics funded by wealthy patrons morphed into a grass-roots movement to decriminalize cannabis made up of less-fortuned Americans keen to support Leary and his legal battles with more modest contributions. As a political movement this was considered to be legally off limits for big philanthropy, which has traditionally stayed clear from such ventures and concentrated on the realms of science and education that are deemed to be politically neutral (Zunz, 2012a, p. 5). Yet, this did not stop a handful of New York millionaires from getting involved in the battle-just like some had to cover "Typhoid Mary" Mallon's own legal expenses at the turn of the century (Bartoletti, 2015).

By looking at this undocumented side of Leary's movement, this paper adds to the history of American philanthropy (Bremner, 1988; Crowther-Heyck, 2006; L. J. Friedman & McGarvie, 2002; 2002; Powell & Steinberg, 2006; Zunz, 2006, 2012a) by examining how both wealthy and ordinary Americans dedicated time and money to benefit the psychedelic community, regardless of its illegal or otherwise deviant practices. In this way, it documents a rather unique case of open psychoactive drug activism that transcended class, which may, in a much larger historical framework, be framed as an early attempt to liberalize illicit substance use before the war on drugs of the 1970s. In a similar vein, this article examines the transition from psychedelic funding to marijuana activism and understands the support for Leary's campaign to prove the cannabis laws unconstitutional as a catalyst for a much broader movement to decriminalize and legalize the drug, and contributes to the history of cannabis politics by underscoring its loose connection with big philanthropy (Booth, 2005; J. C. Davis, 2015; Dufton, 2017; Ferrara, 2016; Lee, 2013).

As well this paper builds on the existing historiography of the 1960s. First, it pays particular attention to the way Leary's movement was helped by a funding process that is considered "a quintessential part of being American" (Zunz, 2012a, p. 3) and adds to the scholarship that has argued that this movement was part and parcel of American culture in spite of its apparent criticisms of the American way of life (Elcock, 2015).[5] Second this side of the history of drug use points to a complex and pluralistic psychedelic culture that could include millionaires as much as ordinary Americans and examining this uncanny involvement of the elites and the mobilization to protect Leary becomes another way of rethinking the boundaries separating part of the 1960s counter-culture and the "dominant" or "mainstream" culture it supposedly took issue with.[6] Beyond these contributions this paper points to the contemporary context of the scientific reappraisal of psychedelic drugs in neuroscience and psychiatry (the "psychedelic renaissance" (Hartgosohn, 2020; Langlitz, 2013; Sessa, 2012) and discusses the historical continuity of psychedelic philanthropy.

1.1 Psychedelic research and patronage

In the 1950s, and before psychedelic drug use became more visible in the second part of the following decade, some medical doctors saw these substances as novel ways of probing the depth of the human mind. LSD appeared to break down mental barriers, ease the process of introspection, and lead to therapeutic renewal. As a result, psychiatrists reasoned that the drug could be a valid adjunct for psychotherapy and used it to treat mental illness and alcoholism (Dyck, 2008; S. Marks, 2015; Passie, 1997). By the late 1950s LSD had generated a considerable amount of scientific enthusiasm that was amply covered in newspapers and magazines (Siff, 2015). In various parts of the country, medical doctors conducted research as part of their scholarly work for universities. Like most investigations undertaken in behavioral sciences, many of those endeavors were funded by the National Institute for Mental Health.[7] But others realized that certain wealthy philanthropists and non-profit foundations could offer them financial assistance.

The private funding of psychedelic science may seem surprising on the surface, given the controversies that occurred in the 1960s, but less so if we look at the trends in patronage in the postwar period and the intellectual and scientific shifts that accompanied them. At the time behavioral sciences laid great emphasis on problem-solving and psychedelics seemed to offer a great deal to tackle various social ills (Stafford, 1967). Historian Hunter Crowther-Heyck has disputed the notion that patrons resented politically controversial topics related to race, class, gender, and religion. For instance, federal and private patronage supported projects that were instrumental in the *Brown vs Board of Education* Supreme Court decision, launching the war on poverty and challenging ideas of sexuality, race, and gender (Crowther-Heyck, 2006, p. 427), and other historians have tempered the hegemonic influence of the Cold War on the funding of research topics in the social sciences (Solovey & Cravens, 2012).

But even then qualifying psychedelics as controversial substances in those early years is debatable. On the one hand, psychedelic research did break away with the behavioral sciences that were increasingly adopting a rigorously empirical "natural science" model for social sciences to gather support (Crowther-Heyck, 2006, p. 426); psychedelic scientists relied instead on subjective accounts of psychedelic experiences to underscore the efficacy of their therapies (Oram, 2012). On the other hand, perhaps LSD was just another substance among the battery of drugs available to Americans in the golden era of psychopharmacology (Healy, 2002; H. Marks, 1997).

Some of these funds were channeled to major organizations dedicated to the study of these substances outside academia. In 1961, the International Foundation for Advanced Study (IFAS) was founded in Menlo Park, California. It gathered a team of researchers to look into the potential of psychedelics and had Charles Savage as medical director from 1962 to 1964. In 1965, Savage became director of research at the Spring Grove State Hospital in Baltimore where seminal psychedelic research was conducted (Oram, 2018, p. 109)[8] and maintained his involvement with the IFAS. On October 8, 1965, he wrote to Nina Ridenour, secretary to the Ittleson Family Foundation, a philanthropic organization in New York City that had been interested in curbing mental illness since 1932. He acknowledged their financial contribution "at a time when support for this study was difficult to obtain" and added: "Even more important to me than the money was the moral support which you provided."[9]

Savage seemed to have realized that philanthropists could be powerful allies for psychedelic research and tried to further court the Ittleson Foundation by sending them a letter describing his ongoing work and suggesting that additional funds would be most welcome. In tune with the objectives of the Foundation, Savage was careful to underline the potential of this study for the greater benefit of society: "It appears that we have developed useful techniques for the brief psychotherapy of chronic neurotics and alcoholics." He also felt that it was "timely to expand the range of therapy to such social problems as addiction and delinquency."[10] On February 15, 1966, Savage scheduled an LSD session for Ridenour to observe on closed-circuit TV on February 24, 1966, so that she could get a better idea of their work.[11]

Other scientific organizations investigating the potential of LSD for mind research enjoyed even better fortunes. In 1963, British expatriate and M.D. John Beresford founded the Agora Scientific Trust in New York City and co-directed it with philosopher Jean Houston. Among the research advisers was *Playboy* executive Victor Lownes (who dispensed the drug to The Beatles' dentist and to filmmaker Roman Polanski) but more importantly, the group could count on the support of Nassau millionaire Howard Teague who, as psychologist Stanley Krippner recalls, had a life-changing psychedelic experience and wished to see these substances used legally.[12] According to Michael Hollingshead, another British expatriate famous for introducing Leary to LSD, Teague bankrolled the organization by helping it acquire property and furniture "in a very open and generous way."(Hollingshead, 1973)

What drove these patrons to give to psychedelic research is not always clear but it is nonetheless possible to suggest four general types of motivations. The first obvious reason was scientific. Psychedelics were promising adjuncts for psychiatry and might be able to alleviate social problems like alcoholism, mental illness, and prison recidivism (Doblin, 1998; Tenenbaum, 1961). Second, libertarian-minded benefactors moved in when authorities tried to ban psychedelics and to sideline Leary because they saw the attacks as a violation of academic and religious freedom.[13] Third, LSD was still an obscure drug in the early 1960s and some philanthropists may have become interested in these mysterious and exotic substances and supported psychedelic research to boost their cultural capital (Ulibarri, 2000; Versterlund, 2006).[14] Finally, those who underwent a life-changing spiritual experience with psychedelics felt that these drugs were so important that they needed to be widely promoted. Where scholars have acknowledged the importance of religion in shaping social movements, charity, and voluntary associations (see, e.g., Hustinx *et al*., 2015; Lam, 2002; Rossinow, 1998) a religious revelation (Huxley, 2004; Nordstrom & Pilgrim, 1980; Shipley, 2015; H. Smith, 1964; Zaehner, 1957),[15] rather than belonging to a religious congregation, could prompt philanthropists to support psychedelic research.

1.2 Leary and the Harvard years (1960-1963)

In the early years of the 1960s Leary was also conducting psychedelic drug research, which became increasingly idiosyncratic as the years went by. At Harvard University's Center for Research in Personality, he saw fit to surround himself with fellow academics as well as lay people and he liberally dispensed psychedelics to Allen Ginsberg, jazz musician Charles Mingus, and poet Robert Lowell, to name but a few. Spurred by Ginsberg's own idealistic enthusiasm, he shunned Aldous Huxley's caution to refrain from promoting psychedelics as magic bullets, particularly after his seminal 1961 LSD experience, after which he concluded that reality was nothing but a cultural consensus (Higgs, 2006, pp. 41-46)

While most researchers into LSD and psychedelics were far more conservative in their approaches to these drugs, psychedelic idealism was neither confined to Leary, nor was his desire to share these substances with non-scientists. Saskatchewan-based MDs Humphry Osmond and Duncan Blewett were thrilled by the possibilities for personal transformation and Osmond and UCLA psychiatrist Sidney Cohen famously initiated Huxley and Henry and Clare Booth Luce respectively (Dyck, 1997; Novak, 1997). But this paled in comparison to Leary's iconoclastic brand of psychedelic research that was intent on revealing the transformative power of these drugs regardless of the scientific method-even though his treatment model did not differ greatly from the accepted methods of the time-and to his ultimate goal of making the world a better place.

Perhaps more importantly Leary and Alpert were both charismatic figures who were able to draw considerable support from a broad range of Americans. In their respective biographies of Leary Robert Greenfield and John Higgs both describe him as seductive, manipulative, and narcissistic-though Higgs' account is generally more balanced and occasionally more sympathetic (Greenfield, 2006; Higgs, 2006). What is less documented is the background of Richard Alpert, who was born into immense wealth thanks to the fortune his father had made in the railroad industry, and the influence he had at Harvard. As Beat poet Gerd Stern remembers, "Richard was probably the most magnetic and the most successful lecturer in psychology ever to teach at Harvard. Psychology 1, or whatever it was that he taught, always needed the largest auditorium, and there was never even standing room available. The guy is a snakeoil salesman of the first order. I mean, he can go on any subject and persuade you that this is absolutely it" (Stern, 2001). More to the point Alpert was described by former Harvard graduate student Ralph Metzner as a "money magnet" because of his ability to attract research grants before his involvement with psychedelics, which in turn enabled him to employ several graduate students (Dass *et al*., 2010).

As the word got around that Leary was conducting mind-altering drug sessions around Harvard and in New York City, a wide pool of supporters became interested in his enterprise and felt that his experiments warranted funding. From 1961 to 1963 he and his associates organized drug sessions with incarcerated inmates with the stated aim of reforming them from within to ultimately set them free and gradually empty the prisons of the country.[16] His prison rehabilitation program certainly appeared controversial on the surface; yet, it was surprisingly in tune with the kind of problem-centered and interdisciplinary research projects the patronage system of the time sought to fund. As Crowther-Heyck puts it, "One important consequence of this belief was the idea that research should focus on solving problems with tangible, testable, real-world implications in addition to having significance for theory" (Crowther-Heyck, 2006, p. 433).[17] At the time both the federal government and the non-profit sector were indeed concerned about crime and their respective funding schemes were supporting the Mobilization for Youth initiative to fight juvenile delinquency on New York City's Lower East Side (Zunz, 2012a, pp. 212, 213). Hence patrons supported Leary's work not necessarily out of psychedelic conviction but because it might be able to tackle a major social issue in a highly innovative and radical way.

This project became partly funded by the Uris Brothers Foundation, created by real estate tycoons Harold and Percy Uris. The grant, which was renewed in 1962, covered clerical expenses and the salaries of former inmates working in the community.[18] The connection between Leary and Uris appears to have been made possible by real estate agent Bernard Friedman, who was drawn to Leary's enterprise as a result of a psilocybin session the latter had conducted for him. Friedman believed that the mushrooms had helped him become "freer, more relaxed" as a writer and he wanted to repay Leary in any way he could. So he spoke with the supervisor of the Foundation and Harvard graduate who was keen to contribute $5,000 to his *alma mater* (B. H. Friedman, 2006).[19] Wall Street stock-brokers also felt that Leary's work could benefit society. In May 1963, Arthur Tomaselli of Arthur Wiesenberger & Company sent them $100 drawn on the Morgan Guaranty Trust Company and acknowledged their "noble cause."[20]

His greatest backers, however, came from the Hitchcock family that boasted a long tradition of philanthropy. Peggy and her brother Billy-a stockbroker at Lehman Brothers-were the grandchildren of founder of Gulf Oil William Larimer Hitchcock, the nephews of the famous philanthropist Andrew W. Mellon, and the children of Tommy Hitchcock Jr., considered one of the greatest polo players ever. They helped him further his crusade by offering financial, logistic, and legal assistance.[21] Peggy became the secretary to Leary's International Foundation for Internal Freedom (IF-IF), an eclectic organization dedicated to the study of psychedelics.

This was but one of the many acts of generosity coming from the Hitchcock family, who soon became critical allies for Leary's venture. Peggy and Billy's brother Tommy sympathized with Leary's cause by donating $2400 toward his research,[22] but his direct involvement remained discreet. Peggy, on the other hand, appeared to be thrilled by the possibilities offered by these drugs and by Leary's psychedelic mission. As the secretary to IF-IF, she sent several letters to members of her family with materials pertaining to psychedelic research, which shows that she was looking to broaden IF-IF's support base by sparking their interest in these drugs. For instance, she told her uncle Jack and aunt Ray Walton, daughter of William Larrimer Mellon and philanthropist, that she was terribly excited by her involvement in psychedelic drug research and by the new scientific possibilities to study consciousness, and underscored the value of such substances for the human race.

Crucially, she also mentioned that the current scientific climate threatened psychedelic research and that it was urgent and critical to lobby the government to ease the situation: "The present need for funds is the result of a ridiculous development, the confusion in Food and Drug Administration regulations following the thalidomide scandal last summer. Virtually all so-called experimental drugs such as LSD-25, as well as numerous others of different sorts, are no longer available for research, due to new FDA restrictions."[23] Her enthusiasm was genuine, according to Leary. Notwithstanding utopian fancies, she understood that LSD could have great value for society: "I know Peggy was very excited at the possibility of LSD knocking out junk habit."[24]

Leary and his associates realized that charity could be a strong source of income and reasoned that they needed to be more attractive for donors like the Hitchcocks. In October 1963, the IF-IF was granted tax-exempt status, retroactive to the beginning of the year. This was an important asset to help the organization secure additional funds and in the process this brand of psychedelic philanthropy furthered a much longer tradition of tax-exemption that is such a fundamental part of the non-profit sector.[25] In two letters, Alpert informed some of the contributors, which included Peggy Hitchcock, of the news and thanked them again for their generosity: "Your gift, made at a time when our need was so great and when we could not definitely assure tax exemption, was doubly welcome. I am happy that from a tax point of view this confidence has been justified."[26]

But in spite of Peggy's generosity, Leary could not always easily have access to some of the funds for his research, likely because Leary was flouting academic conventions and because the university was uneasy about a psychologist (rather than a psychiatrist) dabbling with strange mind-altering drugs. In November 1962 she contributed $3000 toward his "Behavior Change Program" through the Laboratory of Social Relations of the Harvard Faculty of Arts and Science. As arrangements were made to channel these funds to Leary, the Laboratory requested certain provisions which suggested that the university was beginning to treat his research with suspicion. It informed him that they were "not willing to administer funds for their research involving the drug psilocybin unless a suitable committee could be formed to advise on the research and help control the various public repercussions of their activities." As the Laboratory believed that those conditions were not met, it informed Leary that he should request a transfer of the funds out of the laboratory and into an external organization.[27]

It is easy to see why Harvard was pulling the plug on his research, just like medical doctor Thomas Szasz had seen his staff dwindle because of his controversial views on psychiatry around the same time. Initially, Leary seemed like a promising psychologist who had a bright career ahead of him. His interest in psychedelics did raise a few eyebrows, but then the university also had a long tradition of academic freedom, so he was free to experiment with psilocybin. Things changed in spring 1962, however, when the *Boston Herald* tabloid reproduced a damning piece revealing that Leary and Alpert's colleagues were concerned by their lack of scientific rigor and suggesting that these drugs were trickling out of their lab and onto the campus (Gordon, 1962, as referenced in Siff, 2015, pp. 124 and 125). The publicity certainly piqued the curiosity of several students but more importantly the Harvard drug scandal was the first of the kind to make the nationwide news. In 1963, Leary's and Alpert's contracts were not renewed.

Though the university's concern for its reputation explains in part why it sought to impose restrictions on Leary's research, his gradual resentment of academic science can also be attributed to the inherent complexity of the psychedelic experience. Those investigating LSD as an adjunct to psychotherapy relied on the subjective experiences of their patients, rather than on hard, objective, and measurable data. In the aftermath of the thalidomide scandal that had witnessed the drug cause terrible birth defects, which Peggy Hitchcock mentioned in the letter to her aunt, the 1962 Kefauver Harris Amendment of the FDA introduced the requirement to prove the scientific efficacy of a drug before it could be used, which created further constraints for psychedelic research. As historian Matthew Oram has argued, this crippled research to a point where only a handful of government-sanctioned studies were underway by the late 1960s.[28]

It is no surprise, then, that the idiosyncratic Leary preferred to move away from the university and continue his research outside academia. This prompted a gradual metamorphosis whereby he "abandoned the role of the conventional, academic, scientist, and became, without knowing it, a *shaman*, an activist change-agent" (Leary, 1982). Philanthropists did not terminate their funding, however. They reasoned that Leary's research was important, regardless of the epistemological questions surrounding psychedelic science.

1.3 Millbrook and the study of spirituality (1963-1965)

After leaving Harvard Leary wondered where the IF-IF could set up shop and, partly thanks to Peggy Hitchcock's handsome 20,000 dollar donation (Leary, 1990), they initially found sanctuary in Mexico and subsequently in the Caribbean. But in the end, local authorities were unimpressed by a bunch of eccentric Americans using mind-altering drugs (Higgs, 2006, pp. 54-58) and they were forced to temporarily move back to Boston. Before the Hitchcocks offered their assistance once again, Leary was courting the help of another wealthy figure. Early in 1964 Bostonian and Romania-born Elisabeth Amelung expressed her interest in supporting the IF-IF by inviting them to settle on her 55-acre estate. She had experimented with the psychedelic peyote cactus and organic gardening with an experimental commune in Romania.[29]

But Leary soon learned that the Hitchcocks had just bought a 2500-acre estate in upstate New York for tax purposes-it functioned as a cattle ranch so it was also good investment. His group settled down on their property in Millbrook and Leary created the Castalia Foundation to study psychedelics in an even more eclectic setting and with reasonable operating costs-the rent was a dollar a year (Greenfield, 2006, pp. 206, 207). Billy joined and sponsored Castalia and the other two semi-religious institutions that sprouted on his estate. Bill Haines ran the Sri Ram Ashram and former psychologist Art Kleps, who authored a zany psychedelic *Boo Hoo Bible* (Kleps, 1971),[30] directed the iconoclastic Neo-American Church. One observer saw this move as a classic case of philanthropy, claiming that Kleps' unusual Church was fortunate to have such a wealthy protector, who gave it "a kind of establishment gloss as well as a home."[31]

As historian of religion Robert Fuller aptly sums up, the Millbrook scene does not elicit easy interpretation. "For about four years Millbrook was a monastery, school, research laboratory, religious commune, and opium den all rolled into one" (Fuller, 2000, p. 69). What is clear however is that in the post-Harvard setting any idea of rigorously empirical science had gone out of the window. But the transition from behavioral sciences to this unorthodox pursuit of psychedelic-induced spirituality did not occur suddenly and had precedents in Leary's time at Harvard (Lander, 2011, p. 67). In April 1962 he and graduate student Walter Pahnke had studied the effects of psilocybin on a group of divinity students in an attempt to show that the drug could trigger a mystical experience.[32] This naturally paved the way for more emphasis on the religious import of the psychedelic experience, which eventually culminated in Leary's transformation into a religious figure extolling the benefits of LSD in the second part of the 1960s.

With Leary's academic career over and all the negative publicity, the New York elite naturally stayed clear from him and his research, which makes Billy Hitchcock's own involvement all the more intriguing. Kleps, for one, was unsure of his motivations: "Youthful folly? Courage of Psychedelian conviction? Sympathy and generosity? Boredom? Innocence? Arrogance? Curiosity? Lecherous anticipation of variegated choirs of marijuana goddesses? The hypnotic spell of Timothy Leary?" (Kleps, 2005b). Some of the Millbrook residents like Hollingshead never trusted him and thought that it was strange, if not downright suspicious, that a millionaire who was part of the "establishment" could have such an interest in the psychedelic revolution. He sometimes took part in the psychedelic group sessions with Leary and his associates, but unlike everybody around him, he tended not to verbalize his experiences and never came forward with any metaphysical insights on his trips.[33] Hollingshead notwithstanding, other figures of the psychedelic movement saw Hitchcock as a fraud. The less-known Lisa Bieberman ran a series of bulletins for the "Psychedelic Information Center" in Cambridge, Massachusetts-she took part in Leary's venture from 1962 onward, but ended up criticizing Leary and Kleps for their public mismanagement of the psychedelic movement.[34] In her writings, she referred to the case of Tord Svenson who had been ordained "Keeper of the Divine Toad" by Kleps and had helped him financially and physically in many occurrences. But when he was arrested for possession of cannabis and peyote, neither Kleps nor Hitchcock budged to assist him with the legal procedures. She also accused Leary and Kleps of extorting money from their supporters when they requested contributions to cover the legal expenses of bail charges ($35,000) levied against the Millbrook residents in various drug-related arrests:

> Billy Hitchcock has already paid the $35,000 bail charges; his pockets are not empty. He has forty million dollars. He owns and operates the estate for his personal amusement. What he feels like paying for, to keep the carnival going, is paid; what he doesn't feel like paying for, isn't paid. Tord Svenson, for instance, was considered dispensable-in the long run anyone is dispensable except Billy Hitchcock, and whomever he relies upon to keep his scene exiting, which at the moment seems to mean Leary and Kleps.[35]

Others, on the other hand, thought that he was genuinely interested in reforming America. For instance, New York psychedelic painter Isaac Abrams still thinks today that "Billy believed in the psychedelic experience."[36] Others still thought that he was simply looking for an unusual form of excitement. Gerd Stern, who collaborated with Leary for artistic undertakings, contends that "Billy like his sister Peggy was intrigued and became involved in the revolving group of exciting personalities who comprised the culture of Millbrook."[37] In any event, he was a major backer for Leary's venture, who undoubtedly enjoyed fueling this unusual scene at the crossroads of science, religion, and debauchery.

As for Billy's sister Peggy, self-described as a "trust fund baby" who was bored by her upper-class environment, it is much clearer that she was fascinated by psychedelics and enamored by Leary. She had first tried mescaline in 1961 and then heard about his research into mind-altering drugs courtesy of the influential theater producer Van Wolfe (Dass *et al.*, 2010, p. 42). Peggy admired Leary's spirit of adventure and enterprise and soon fell in love with him. For a womanizer like Leary the feeling was not mutual but they nonetheless became close friends and occasional lovers. In spite of the money and energy she gave to Leary's mission she was surprised that he never really openly solicited her for greater funding: "He never asked me for money. I think he felt he had to make it on his own [...]. Perhaps he also had a cultural bias because I was a woman with whom he was involved and he would not feel comfortable asking me for money" (Dass *et al.*, 2010, p. 58).

Theology professor Walter Houston Clark was another prominent contributor, who was likely driven by a combination of Christian charity and the strong impression the psychedelic experience made upon him. He gave $150 toward Leary's research after spending time with him at Millbrook in 1964[38] and he was rumored to be much wealthier than he appeared, but with the reputation of being stingy. Yet, when Kleps was arrested in Florida for possession of LSD, Clark gave $200 for his bail. On another occasion, Kleps was visited by a young couple that was touring the United States listening to gurus and experimenting with psychedelics. In his own words, they "were ragged and appeared to be poor," but turned out to have substantial income from trust funds, and ultimately "outcontributed Billy Hitchcock ... by about 20-to-1 in the years that followed" (Kleps, 2005d).

The less-known Charlie Rumsey got involved in Leary's movement. For Kleps, his role in New York's psychedelic scene seen has been underestimated: "Psychedelianism will truly have triumphed on the day when the sun's early light dawns in Central Park on a statue of Charlie" (Kleps, 2005e) Rumsey was an old friend of Hitchcock's and a lawyer who came from an equally wealthy background and had ancestral connections with the Harriman family that had built its fortune with the railroad industry and that was also involved in philanthropy. He led an eccentric and flamboyant life and liked to entertain in his New York apartment. For those in the know, however, he became an important LSD supplier for the wealthy and guided many LSD users toward the Millbrook commune. And when Leary ran into trouble with the law, he was one of the many New York jet setters to help the defrocked Harvard professor-by becoming secretary to the Timothy Leary Defense Fund.

1.4 From charity to activism: The Timothy Leary defense fund

In December 1965 Leary was arrested on the Texas-Mexico border for carrying less than an ounce of cannabis. Facing a 30-year prison sentence, he decided to take his case to the US Supreme Court and argue that the 1937 Marihuana Tax Act was unconstitutional. In March 1966, Billy Hitchcock provided Leary's bail money and then set up the Timothy Leary Defense Fund (TLDF) to cover the legal expenses of the upcoming trial. The TLDF published a call for donations in the *New York Times* (Lander, 2014, p. 147) and sent letters all over the country, hoping to gather enough financial support.

As a result one of the psychedelic movement's major sources of income began to shift away from the wealthy philanthropists to a more grass-roots form of campaigning, which involved collecting more modest contributions from less-fortuned Americans. Up until his first arrest, patrons had been supporting Leary's research that many saw as idiosyncratic, but not illegitimate. When they moved to defend him and to contribute to his Defense Fund, they decided to condone his use of cannabis and shifted away from a longer tradition of "scientific philanthropy" (Bremmer, 1988) to promote a form of pro-drug activism that lacked the moral sanction of scientific research. Additionally, Leary's cause converged with the Committee to Legalize Marijuana (LeMar) initiated by Ginsberg and poet Ed Sanders in December 1964, and which argued against the prohibition of cannabis on libertarian and medical grounds (Ed Sanders, 2011).[39] What had started as a charity-based scientific enterprise morphed into a social movement that was in tune with the climate of the middle of the decade.

To be sure, Leary's high-profile exit from Harvard was a source of publicity that helped gather support. For artist Martin Carey, "The '50s were such a dull, sleepy time, and school was dull and boring and inoffensive.' The people who had trouble in school were usually more intelligent, so they got bored." Hearing about a drug scandal in an Ivy-league institution-it "was like a light shining into all that boredom" (Graboi, 1991)[40] Yet, Leary's crusade would not have been the same without the backing of the New York jet set, rather than the so-called "Flower Children" of the second part of the 1960s, and the TLDF secured funds through a letter-writing campaign that was hardly unconventional. Historian Lisa McGirr has studied the history of conservative activism in Orange County, California (where Leary was, incidentally, arrested again in 1968 for cannabis possession) by examining the grass-roots role of ordinary middle-class suburbanites who pressed for a conservative agenda, which also included writing letters (McGirr, 2001). Just as McGirr lamented the disproportionate focus on the liberal and progressive movements of the 1960s at the time of her publication, a more balanced take on one of the most controversial movements of the decade reveals classic tactics and backers, rather than just radical and provocative statements and actions.

In the larger history of the psychedelic movement, Leary's 30-year conviction for cannabis possession and his subsequent defense is critical to understand the latter part of the decade. Notwithstanding the convergence with LeMar, it also saw him complete the transition from academic psychologist to High Priest of LSD that had begun in the aftermath of the drug scandals at Harvard. This was not just the result of a discussion with the famous Canadian media analyst Marshall McLuhan, who had advised him to make his discourse fashionable and appealing to gather popular support. As his lawyer pondered how to defend his case, Isaac Abrams, who happened to be visiting at Millbrook, came up with a brilliant idea: "Well, American Indians take peyote as a sacrament. Maybe this is a similar thing." The attorney was thrilled. "And the next thing you know, they were calling it a sacrament."[41] By presenting cannabis as such, it opened up a new legal strategy: Leary, as an alleged practicing Hindu, could invoke his right to use the drug as part of his religion.[42]

So the language of "rights" became one of Leary's favorite angles of defense (Elcock, 2015). This contrasted with the rhetoric deployed by another psychedelic icon. Novelist Ken Kesey, famous for writing *One Flew over the Cuckoo's Nest* and for organizing seminal psychedelic parties on the West coast, had also been arrested for cannabis possession on April 13, 1965 in his home in La Honda, California. A Ken Kesey Defense Fund (KKDF) was set up to cover the legal expenses, because the high bail had drained his resources. Although the KKDF courted contributors by invoking the duty to protect the rights guaranteed by their American citizenship, Kesey himself preferred to mention the broader atmosphere of protest that reigned throughout the country:

> I think people all over the country are getting fed up with the way officers of the law have been treating 'outsiders' recently. They're sick of the way police brutally beat young civil rights workers in the South, sick of the methods used by police during the recent demonstrations on the Berkeley campus of the University of California and fed up with the way police officers have been harassing creative groups such as we have here in La Honda [...].[43]

While the legacy and impact of the KKDF is hard to assess due to the lack of primary material available, it appears that the TLDF drew a wide range of support from all over the country. Students, computer programmers, biologists, teachers, postal clerks, or physicists gave to the cause out of libertarian convictions[44] or out of disgust at the harsh sentence passed.[45] Others requested further information on the legality and pharmacology of psychedelic drugs and cannabis, and expressed interest in the idea of reforming drug laws.[46] Others still wished to remain anonymous, but contributed financially and gave lists of names to contact on their behalf.[47] Anthropology professor Omer C. Stewart, who had previously testified as an expert witness in cases involving peyote, was another donor who did not want to see his name appear on the list of public figures supporting Leary, but agreed to support the Fund confidentially.[48] Although the TLDF was based in New York City, the organization was eager to expand and set up chapters in other cities. In Washington, D.C., several supporters formed the Psychedelic Information Center of Washington, which ran newsletters to raise monies or simply collect donations for the Fund.[49]

The TLDF also sent letters to progressive groups, hoping for support from more typical organizations to defend Leary's rights. The Bruin Humanist Forum, a University of California at Los Angeles chapter of the Humanist Union of North America, expressed its sympathy for Leary's cause and supported him by disseminating information about cannabis and LSD, and was also interested in the broader issues: "We are eager to help in the fight to legalize marijuana."[50]

In an attempt to connect pro-drug activism with the trademark protest movements of the 1960s, the Defense Fund tried the American Civil Liberties Union (ACLU) that had previously assisted several progressive causes of the 1960s. In 1961 the Southern California chapter had for instance put pressure on the Board of Education to fight school segregation and overcrowding in Los Angeles (Theoharis, 2006) and in 1966 Native American Indians and the nascent Red Power movement likewise found its legal support in 1966 when activists were arrested as a result of their involvement in the "fish-ins" in Washington State to protest against the violation of a 19th-century treaty guarantying their rights to fish in the area (S. L. Smith, 2012).

But when the right to consume illicit drugs arrived on the agenda, the reactions were mostly negative, if not openly hostile. Many ACLU members simply requested to have their names removed from the mailing list and wondered how the TLDF had gotten them in the first place. One member of the Union admitted that Leary's conviction was an extreme sentence, but he felt that he would never have to do more than three years and that at any rate Leary was "largely responsible for the present widespread, uncontrolled use of LSD, especially by young people with well-documented disastrous results in many cases."[51] Another member argued that Leary had repeatedly broken the law and led others down that path and that for that reason he "would gladly do anything [he] could to uphold Timothy Leary's conviction."[52] Another still was brief and blunt: she declined the offer to contribute to the TLDF but on the other hand she was willing to send funds to ensure his imprisonment.[53] Such antagonistic reactions were even stronger than the kind of "liberal anticommunism" that plagued the organization (Kutulas, 2006), so for once Leary was not far off the mark when he wrote around the same time that mind-altering drugs were so reviled in America that they were "a symbol more powerful than sex or communism"(Leary, 1995).

Unfortunately for Leary the TLDF closed on May 27, 1966, due to lack of funds.[54] Despite the many contributions, administrative and legal expenses were too high to be effectively met. Additionally, Leary and his crew were raided in their Millbrook home on April 17 and many were arrested for drug possession. Posting all those bails was a critical blow to the Fund. The three religious leaders, Leary, Kleps, and Haines co-authored the "Call to Alms for the Battle of Millbrook," in which they requested donations for the Millbrook Defense Fund (Kleps, 1971, p. 63), and contributions continued to come in, but at an average of $10 per day.[55]

1.5 The legacy of the TLDF

In spite of its shortcomings the TLDF became a catalyst for the broader campaign to legalize cannabis use. The support Leary received for his defense was not surprising in that marijuana activism had been going on for a few years in New York and was burgeoning in California, where Los Angeles attorney Al Mathews was mounting a challenge with the Anonymous Committee for the Abolition of the Prohibition Against Marijuana by collecting signatures for a petition. They put forth pharmacological arguments that criticized the legality of alcohol and tobacco, when cannabis seemed less harmful and potentially therapeutic.[56]

Leary's strategy inspired some cannabis users to challenge the legislation in a similar way. In September 1966 Mark Fox wrote to the TLDF to request information about Leary's defense because he was awaiting trial in Arizona for possession. Like Leary, Fox was keen to invoke the language of rights to defend himself: "I expect to admit to smoking marijuana but will try to show that it is my right as provided by the U.S. constitution."[57] Howard Ingram was in an even worse situation in California, facing trial for selling the drug to a minor and possession of cannabis and LSD with the intent to sell. He wanted to take his case to the Supreme Court, if he could gather enough support, and was keen on monitoring the Leary case, in hope that his defense would set a legal precedent.[58]

The convergence of psychedelic voluntary associations and the pro-cannabis movement was even more apparent when LeMar received a copy of the TLDF's Declaration of Principle through their attorney, which they signed and returned. The state of their finances did not permit them to contribute to the campaign, but they promised to help by requesting forms to be sent out to the LeMar mailing list across the country.[59] But even more fittingly Mike Lynch wrote to Leary in the fall of 1966 to tell him that he would like to start a LeMar chapter at the Arizona State University and requested "all the historical, legal, social, and scientific information [about] marijuana and LSD."[60]

The psychedelic movement and the TLDF appeared to spur the larger psychedelic counter-culture to jump to the defense of its fellow drug users. The support was often morally justified by the fact that defendants were sometimes entrapped by undercover law-enforcement officers and then faced harsh penalties for use or distribution of the drug. Sometime in spring 1967, Jim Ewan, who was serving as "Boo Hoo" for the Neo-American Church chapter at Wichita State University in Kansas, was entrapped by two FDA agents and charged with possession, sale, and delivery of LSD, and possession of cannabis. A defense fund was set up and calls for legal and financial support were made in the pages of the *East Village Other*. The New York underground newspaper-very sympathetic to psychedelia-stressed the importance of fighting for the case from a religious perspective, just like Leary was doing: "If the psychedelic churches are to hope for any legal acceptance of their use of these sacraments, they should realize the importance of this case, the best test case at present" (*East Village Other*, 1967).

Similar organizations were established throughout the entire country. In Chicago, the Drug Reform Union made plans to offer drug users legal aid and bail money "so that the busted person can obtain legal advice and bail to get him out of jail as fast as possible" (*Daily Illini*, 1969) In 1967 Kleps was arrested in Florida and Lisa Bieberman raised $1000 for his bail through her LSD Loan Fund-"only to have him retreat into Millbrook and refuse to appear for trial, thus causing [her] to lose most or possibly all of the bail money."[61] The LSD Loan Fund also lent one psychedelic drug user $150 to help him with his legal expenses, following his arrest for possession of peyote and cannabis in North Carolina.[62] As well, the magazine *Innerspace*, which was created as a national platform for the psychedelic culture, requested financial assistance for a cannabis user who was arrested in Capitola, California in February 1966 for possession.[63] The magazine offered information about the Jade Companions of the Flowered Dance, which was set up in New York City (with three centers in Manhattan and Brooklyn) to assist psychedelic drug users who had been arrested for drug-related violations of the law: for a $5 annual membership, one had free legal consultation and access to a bail fund in cases of psychedelic drug possession. A similar organization had been established in Washington, DC before the Jade Companions.[64]

As these instances suggest, understanding the rise of this unusual form of humanitarian idealism requires paying attention to the legal status of LSD and other psychedelics. New York State provided penalties for possession and distribution of LSD as early as 1965. The drug was banned on October 6, 1966 in California and the federal government made it a Schedule I drug in 1970, which left psychedelic drug users potentially facing lengthy prison terms. Bails and defense funds were set up to give LSD users a chance to fight for their case in court and became the logical consequence of the new legislation. But in spite of their efforts, the war on drugs of the 1970s dealt a significant blow to these psychedelic enthusiasts.

However, this psychedelic activism was not just the result of a more punitive legislation. A full-blown psychedelic experience was often interpreted as a spiritual revelation and spurred several psychedelic drug users to act not only for the psychedelic community in its largest sense, but also for what they saw as a great benefit to humankind. As with more orthodox forms of religion in the United States, psychedelic spirituality extended beyond simple spiritual practices and into the secular sphere through acts of charity. In this way, psychedelic philanthropy differed from many other forms of charities and voluntary associations, because the desire to improve society was not motivated by the belonging to a religious congregation, but in many cases by a revelatory drug experience.

1.6 Psychedelic philanthropy beyond the 1960s

In the following decades, LSD and psychedelic drug consumption carried on in the United States, albeit without the idealism of the 1960s. Psychedelic research was virtually non-existent due to the new legislation (Spring Grove was the outstanding exception) and philanthropic attitudes toward these drugs seemed to have disappeared. In the 1990s, however, the rise of the neurosciences rekindled the scientific interest in psychedelics and led to a form of "psychedelic renaissance," which was accompanied by a scientific philanthropy that echoed the enthusiasm of the early 1960s.

Anthropologist of science Nicolas Langlitz has since chronicled this renaissance and has shown that wealthy patrons have been instrumental in facilitating the process. In particular, John Gilmore, a wealthy Silicon Valley libertarian committed to defending civil rights, gave millions of dollars in an attempt to make psychedelics available for medical applications. This, he felt, could ultimately end the war on drugs. And the late Bob Wallace of Microsoft was another major donor to the contemporary psychedelic cause. He almost single-handedly sponsored the research undertaken by the Heffter Institute that promotes research into psychedelics. But unlike Gilmore, he was ready to bankroll both the basic scientific research and the Institute's infrastructure. Most donors longed to see these substances used to treat patients and gave accordingly. But Wallace was well-aware that the process was much longer and frustrating and he donated to the cause while hoping that clinical trials would someday follow suit (Langlitz, 2013, pp. 69-77).

Other international organizations like the Multidisciplinary Association for Psychedelic Studies (MAPS) also illustrate how psychedelic philanthropy survived the 1960s. In 2014, for instance, MAPS issued a press release acknowledging donors who had contributed toward scientific investigations into the potential of psychedelic drugs. The organization received $1.9 million from the late Precious Moments artist and psychedelic enthusiast Timothy Butcher who, in the words of a close friend, "believed strongly in the work MAPS is doing."[65] In one newsletter, the organization thanked several people who gave funds for research but one name stood out: "We also gratefully acknowledge the Rockefeller Brothers Fund, who made a grant of $10,000 to honor Richard Rockefeller and his commitment to philanthropy, or 'love of humanity.'"[66] This of course echoed the financial contributions coming from the heirs to the Mellon family half a century ago and shows that what might have seemed like an unusual cause to support for such a big name in the realm of philanthropy back then was in fact not an isolated case.

There is also historical continuity in the way some psychedelic drug users are organizing to protect what they see as their rights to alter their consciousness regardless of the legislation. In particular, the International Centre for Ethnobotanical Education, Research and Service (ICEERS) created an Ayahuasca Defense Fund (ADF)[67] in 2015 to offer legal advice and support for people (lawyers and expert witnesses) who have been arrested for possessing the DMT containing brew that originates from the Amazon basin. Unlike the TLDF, however, the ADF is much better organized and international in scope and it can cite centuries of indigenous ayahuasca use as proof of its safety and efficacy. Hence the ADF has successfully assisted dozens of defendants in Spain, Chile, the United States, and the United Kingdom, and is constantly looking for financial support to further its cause (Oberhaus, 2017).

Meanwhile, cannabis activism is scoring important victories in the United States and North America and it seems like it is only a matter of time before the plant becomes legal on a federal level. In the process, marijuana has already become a multi-million industry attracting investors from all over the country-a remarkable feat which would have seemed like a pipe dream in the 1960s. But an even larger look at the funding patterns behind the entire category of psychedelics reveals that a similar shift might be underway. The UK-based Compass Pathways, which was created in 2016, has come under fire for using private funds in an attempt to develop a for-profit model of psilocybin therapy and the more obscure Eleusis has recently patented a form of LSD therapy for Alzheimer's disease (E. Davis, 2018). This has prompted some prominent members of the global psychedelic community to release a statement emphasizing the need to conduct psychedelic research with "intellectual and scientific integrity, service, open science and open practices, and non-interference" (Jesse, 2018).

Whether this for-profit model will prevail at a time when post-prohibition scenarios are becoming increasingly plausible is a matter of speculation, but the controversy and uproar suggests that the kind of idealism that had permeated Leary's research into psychedelics has survived the 1960s and is here to stay. A non-profit organization like MAPS, however, epitomizes the continuity of a charity-based and idealistic psychedelic research coupled with a discourse that underscores the value psychedelic drugs possess for humanity, while the global psychedelic community is singling out controversial organizations like Compass Pathways and Eleusis for their unethical for-profit motives.

2. Conclusion

In spite of their flawed and controversial nature, then, Leary and his movement were instrumental in framing psychedelics as revered life-changing tools that should be made available to everyone and that attracted like-minded donors. Where many takes on the history of Leary's psychedelic movement have emphasized his irresponsible promotion of psychedelic drugs, this paper has instead examined how conventional philanthropic attitudes were able to support him and other research groups. Some patrons underwent life-changing psychedelic experiences akin to a spiritual awakening and decided that psychedelics were important substances that deserved adequate promotion. Others realized that these chemicals could benefit society and they furthered a long tradition of scientific philanthropy. Still, others were drawn to the excitement and prestige of becoming the benefactors and protectors of the psychedelic movement. Finally, many psychedelic enthusiasts perceived the attacks on psychedelic research as a violation of academic freedom and defended them on libertarian grounds. The support Leary drew for his research should not really come as a surprise if we look at the major aims behind private patronage in postwar America, which could indeed include behavioral research into a category of vision-inducing drugs that went on to become controversially associated with deviance and dissent.

Though Leary's movement and his high-profile crusade to challenge the existing drug laws stood out, many similar groups felt they were part of a large community of illicit substance users and realized that they needed to organize to inform and protect their fellow members who wished to carry on their psychedelic lifestyles regardless of the legislation. Paying attention to these groups shifts attention away from notions of drug use as escapism and subversion of authority and points to more complex patterns of social bonding within the drug culture. As David Farber has contended in his work on the American counter-culture, "historians need to write more about the men and women who tried, often with qualified success, to build a new culture in the late 1960s and early 1970s" (Farber, 2013, p. 3) and focus away from the famous counter-cultural events that fuel the declensionist (or "rise and fall") theory of 1960s historiography. A history of the funding and support behind the psychedelic movement indeed reveals that many Americans did not see LSD in terms of hedonism, but rather as a useful tool that could benefit humanity and chose to fund psychedelic research and help the psychedelic movement accordingly.

Endnotes

1. Marijuana is often defined as a minor psychedelic, even though this classification is debatable. In this paper, I have chosen to include it in that category of illicit drugs because both LSD and cannabis were linked by their ability to spur Americans to give money for research and activism. Although psychedelics are indelibly associated with the 1960s, heroin and amphetamines were equally prevalent. See for instance the relevant sections in Schneider (2008), Rasmussen (2009).
2. Here Leary's movement is framed at the crossroads of scientific research, religion, and politics. Leary was initially interested in the study of psychedelics but he soon displayed a tangible religious discourse that could also be understood as a political crusade. Certainly, the campaign to save Leary from the hammer of justice was political in nature.
3. As examples of this critical school, see Jonnes (1996), Marwick (1998), Paglia (2003), Heath and Potter (2006), DeGroot (2008). These contributions come from a pool of conservative, libertarian, and liberal authors, which suggests that the repudiation of Leary's psychedelic movement does not stem from political bias.
4. An exception to this trend is Hartogsohn's recent focus on Leary's popularization of the concept of set and setting, albeit from the perspective of science history in Hartgosohn (2020).
5. It strengthens this brand of historiography by highlighting the "American" characteristics of the psychedelic movement, rather than its radical and revolutionary aspects that have attracted the bulk of scholarly attention.

14. A focus on cultural capital and drug use would make for an interesting enquiry into the dynamics of drug cultures. A good illustration of this phenomenon is Henri Luce and his wife Clare Boothe who both enjoyed sampling LSD in the company of Aldous Huxley and philosopher Christopher Isherwood, but who would prefer that the masses stay clear of it.
15. he moral validity of drug-induced mysticism has been debated for over half a century. Psilocybe cubensis „Albino A+“

Macroscopic feat.:

Cap/Pileus: Very pale cream, especially in the center, to white often with bluish tones, sometimes with a sharp central nipple. Universal veil remnant spots are present but inconspicuous against the pale cap.
Gills/Lamellae: Attachment adnate to adnexed. Grayish coloration in young fruit bodies becoming nearly black in maturity.
Stem/Stipe: Similar in coloration to the cap, bluing intensely with damage. Partial veil leaves a persistent membranous annulus that is soon purple with spores.

Microscopic feat.:

Basidio/Spores: Dark purple in deposit.

Habitat: Bovine, Equine Dung and Enriched Soils.

Comment: Unlike the PF albino, this mutated strain retains normally pigmented spores. Since there is also a small amount of pigment in the carpophores, this strain is better considered a leucistic form instead of a true albino.

Psilocybe cubensis „Amazonian“

This Amazonian strain produces very thick and fleshy mushrooms. Although it is not the easiest strain to grow it may, if properly managed, produce some very nice flushes. The number of mushrooms may not be very big, the size more than compensates for this. Fruitbodies are very solid and have a massive stem.
Cold-shocking is definitely required for this one or else the mycelium will completely cover the casing and this makes watering impossible. This condition also causes mushrooms to only form on the sides of the trays (which will lower your yields)
The mycelium of this strain is extremely rhizomorphic.

Psilocybe cubensis „Argentina“

This magnificent Cubensis argentina produces massive amounts of shrooms, is of mediocre size and flushes and flushes forever.
This strain has been known to grow on alder wood and fruit, compost, straw, dung, rice and it's apparent favorite, bird or finch seed. Not only does it thrive during indoor breeding, it also has a very pleasant appearance and is very easy to breed. It will certainly produce lovely prints.

Psilocybe cubensis „Australian“

Hello fellow mushroom enthusiast. This strain of cubensis was picked by BIO in Australia some years back and produces some very healthy, classic text book, golden top cubensis. It has potential to grow some very large fruits at times. Sometimes excedeing 1 foot in height on simple substrates such as birdseed. Usually it will produce a varied amount of vary large fruits, or a huge abundance of average sized fruits, using the substrate very well. On DB compost it we have seen it produce fruits over 18" tall. This strain does excellent on DB compost. Its colonizing speed is average, not breaking any records, but certianly not slow. Another nice characteristic of this strain is it produces very thick, solid stems. We have also found over time this mushroom is very comparable to the ecuador cubensis in many aspects.

Psilocybe cubensis „B+“

The infamous B+ strain of cubensis... what a chameleon this one is. This is by far the most versatile cubensis we've ever seen. Adapting and growing in such a wide range of temperature conditions and substrates. It truly thrives to spread its seed, which by the way its a very heavy spore depositor. Not only does it grow easily indoors, we've seen the B+ fruit outdoors several times in a wide range of temps and substrates. Several times one winter, night time low of 45F, day high of 60F, the B+ just flourished. Spring/summer, low of 75F, high of 90F, the B+ once again fruited beautifully. We've seen it grow on alder wood and fruit, compost, straw,dung,rice, and it especially loves bird/finch seed. We've heard so many good reports back from ppl that just love this mushroom and how easy it grows, and how beautiful it is, its loved by many.
Although the B+ is not a super fast colonizer, its speed is average, producing some very large mushrooms that are generally a caramel color. Grown in cooler temperatures, it usually always produces a very beautiful color caramel cap and stems. The stems are generally very thick, and it produces some large caps. It also drops a very thick veil. Grown in warmer temps, its color changes to a more golden color at times.
The B+ cubensis has been around for a while. It was brought to us by a grower that went by Mr. G. There was a lot of controversy surrounding this mushroom for so long because Mr. G started off by telling everyone it was an azure/cubensis hybrid. Although at times it does grow some broadly umbonate caps like *Psilocybe azurescens*, it is just a unique cubensis. But a huge thanks to Mr. G, where ever you are these days, for bringing us such a beautiful mushroom. We like to refer to this one as "super strain". It really is a superior cubensis in many ways.
This is a Hawk's Eye Favorite and belongs in everyone collection!
These were grown outdoors in a greenhouse, on a mix of 2:1 finch seed to vermiculite, then cased using the 50/50+ tek and mix.

Psilocybe cubensis „Blue Meanie“

The Blue Meanie strain is kind of mystery strain to me.
"Blue Meanies" which is a widely known name for Pan cyan for about 30 years seemed to become also a kind of new cubensis strain. Sometimes a certain vendor renames a strain for I guess commercial purposes. The Z-strain seems to be such a kind of strain. But no one seems to know what strain it should be. It looks a little like the Golden Teacher, but it isn't.
Well we found this strain on some respected vendor sites as a cubensis so we are ready to put this strain on the list.

Psilocybe cubensis „Brasil“

This strain has its origin in Brasil. It's a very rhizomorphic and strong colonizer with medium sized mushrooms. It fruits very fast and appears in clusters counting a large number of mushrooms. No need to isolate this strain to get good results!

source - www.fsre.nl

Psilocybe cubensis „Cambodia“

This is by far one of the fastest colonizing strains of cubensis we have ever seen. We've given it to a few other ppl who witnessed the same results. Let me give you an example. 3 days after inoculation, the strain germinated and 100% colonized 1/2 pint finch seed/verm jars in only 7 days. It was then cased and started pinning 10 days after being cased with a 1" thick casing layer. Mushrooms were harvested 25 days after inoculation. Every patch we've planted has given us the same amazing results...this strain just thrives to spread its sacred seed. We've seen a lot of different strains of *Psilocybe* mushrooms grow over the years.. but this one takes the gold metal for one of the fasted growing cubensis.

Not only do they grow extremely quick, but produced some absolutely beautiful textbook cubensis. This cubensis was originally picked by John Allen while in Cambodia filming some of the *Psilocybe* mushrooms that are growing there. We have also found this to be one of the most potent cubensis we've ever eaten, delivering a very nice energetic high that tended to last quite a while. Its not an extremely intense experience, just very energetic and last a long long time. Very smooth as well without much body noise. This one really wakes you up in a beautiful way. If you like the energetic journeys from these mushrooms, this is your ticket to an all night exploration.

John Allen and his film grew said they found it to be very potent for a cubensis as well.

These cubensis along with some *Copelandia cambodgeniensis* grow in the cattle (brahmans) dung around the Angkor Wat Templeat Siem Reap, Cambodia.

You can see more pictures of this mushroom taken by J. Allen at spiritplants.com.

As for cultivating conditions, it does really well on finch or birdseed, eats through grains, fruits on dung well, loves compost, and seems to love high temps. We've had this mushroom colonize rapidly in 85f+ temps.. and fruited at 93F+ temps with no problem. It loves heat!!!! It also generates lots of heat, so take this in to consideration when incubating and fruiting. This is definitely the summer mushroom of choice. We've also heard back from ppl that the jars of mycelium put off a lot of heat.... not many mushrooms do well in those high of temps.... definitely your outdoor late spring/summer strain. It took a while.. but we have domesticated this strain... and its very stable now, it also withstands contamination very well.

Recently a lot of pictures have been surfacing of this cub doing very well in outdoor patches at cooler temperatures as well. Another thing we have noticed and heard back, is sometimes it produces nice smooth stems, and beautiful caps, textbook cubs, then other times it produces some lumpy stems. They also produce and abundance of mushrooms in a small area. Not a very large growing mushroom on grains, but produces some very large fruits on dung or compost. On grains they make up for the small size by produces a lot of mushrooms in a small area. Be sure and check out the pictures of the cambodians on compost below, this mushroom produces some really beautiful fruits.

For colonization, we recommend 75F-80f, not much higher because they throw off a lot of heat. For fruiting, it will fruit in lower temps of 60F, but it loves heat once again... fruiting will occur from 60F to 93f+.... yes.. 93F+ :) This is one of our favorite cubensis strains because its so fast colonizing and fruiting and is very easy on the mind, body and soul.

Psilocybe cubensis „Cambodian Gold“

The Cambodian Gold is a F1 hybrid of Psilocybe Golden Teacher x Cambodia. This strain is developed by a dutch Growkit producer to immediately start growing a variety of the iconic Golden Teacher strain at home.

It has long been a dream for this producer to provide an easy-to-use grow kit for *Psilocybe cubensis* Golden Teacher, but the strain underperformed and seemed unsuitable as a 'Ready-To-Grow' box. However, through a process of controlled mycelium growing and careful selections, the spores of Cambodia and Golden Teacher were brought together as a powerful cross with hybrid vigour that is called "Cambodian Gold".

The Cambodian Gold was first introduced as a 'Ready-To-Grow' box at Azarius!

Psilocybe cubensis „Colombian“

This one has a nice history from our friend Plankton88 in Colombia who sent us the spores earlier this year. He picks this strain from the cowfields of the nearby little village Villa de Leiva. He personally found them to very potent and a beautiful journey and wanted to help spread the seed if this wonderful cubensis.
There were 2 strains of cubensis sent to us, one from Guato and this one from Villa de Leiva. As for the growing parameters, its a very fast colonizing strain. This strain tends to grow a mix of rhizomorphic mycelium, and cottony mycelium, (multi spore inoculation)yet grows very fast. The strange thing is that when this strain fruits, the mushrooms cant hold their own weight very well. They topple over. Our growers have grown this mushroom several times and find this very interesting why they don't stand up. We need your help with this one. So many mushrooms to cover.. so much energy being spent. As you can see they grow rather large and in huge clumps, rather cool looking I think. We would like to hear your feedback. We're offering this one at a discounted rate just to get some feedback.
As for the high, very clean, yet somewhat mellow. It is a great "social" mushroom. You get the beauty of the mushroom high, yet its very mellow and smooth. Very easy to talk in groups of ppl on this one without feeling to overwhelmed by the psilocybin experience on the psyche. A very "low anxiety" mushroom. It comes on very mellow, slow and smooth. Its great for being around a lot of ppl without having that "high anxiety" feeling of restlessness some mushrooms give. Count on an easy going peaceful journey. This coming from only one experience on these. You be the judge, feel free to send us any feedback you have for this new strain from Colombia.

Psilocybe cubensis „Ecuador“

Coming to you all the way from 3500+ feet up in the Ecuador mountains is the beautiful ecuadorian cubensis. This one was picked by BIO, and is very widespread around the world at this point :O). Spread that seed to the wind brother. This mushroom has become very popular in many cultures as it grows very easily in nature. It also produces some very nice golden color mushrooms and it has been noted by many to be one of the most beautiful, picture perfect cubensis out there. Out in nature under God's grace, it produces an abundance of nice big healthy mushrooms.
According to our friends in Ecuador who eat this mushroom, the euphoric sensation it creates is a very dreamy, relaxing, and can be quite visual.

Psilocybe cubensis „Ecuador Yosterizzii“

This strain came from Mushroomtroll. He gave the following description.
Psilocybe cubensis ecuadorian var. Yosterizii it has a very noticeable wood grain and linear line on the cap some are w/out annulus. It took about 3 years to develop it, and it is a repeating flusher (if you keep your incubator free from parasite you will get a flush every 2 weeks for about 6 month, this strain does not require a casing but is a must for repeated flush (I usually lay perlite at the bottom 2 inch and add 1 inch of water that is presterilize, lay a 1/4 inch of colonize grain over it and then cover with 1 inch of peat moss. (The peat moss is watered to the point were only a few drops of water is running between my fingers and then sterilize.)

Psilocybe cubensis „F+“

Originated from a wild Florida *Psilocybe cubensis*. Isolation was carried out and ended with a cloned fruit. All F+ lineages come from this clone.
The strain is very aggressive and colonises most substrates in exceptional time. F+ has even been fruited from wood chips. Like most cubensis, F+ does best on horse and cow dung. The mycelium of F+ is predominantly tomentose to intermediately linear, although it can grow very rhizomorphically under certain conditions. Despite the predominate tomentose growth, F+ usually pins prolifically.
The fruits from this strain have the ability to grow rather large.
Defining characteristics of this strain include: mycelial spots on cap, symmetrical caps, mycelial growth well along the stem, and an umbilicate cap.
Joshua who isolated this strain hopes that all will enjoy it and that it will be spread to mycologists throughout the world.

Psilocybe cubensis „Golden Mammoth“

Well, there is a lot of Internet gospel going on about this strain. Here are some info's we at FSRE have collected. A commercial vendor in Canada is the only source claiming this strain. On there website thy have the following info's:

"'*GOLDEN MAMMOTH' (psilocybe aureus tantus) is the ultimate, amazing Psilocybe cubensis strain. The Golden Mammoth has earned itself a reputation as the best among Psilocybe cubensis magic mushrooms strains, the most prolific, reliable and resistant study available.*
Developed 13 years ago by an expert mycologist with over 30 years experience, the Golden Mammoth strain arose after extensive research. Professionally perfected, the Golden Mammoth has a pure lineage and virus free genetic line. The Golden Mammoth is the strongest, most vigorous Psilocybe cubensis strain in distribution. This strain delivers mammoth amounts of research material. General Appearance: Gold colored cap. White veiled stem 8"-10" tall."

Whatever the story is behind this strain, we at FSRE can confirm that it's not a rename of the B+ or Golden Teacher. This strain shows his own unique characteristics. And we do belief that this strain is the result of hard work from a professional mycologist.

Psilocybe cubensis „Golden Teacher“

Class is now in session. Eat a few caps and prepare for your cosmo highway lessons! There is a lot of uncertainty as to where this strain originates from. Its believed to come from a company out of Amsterdam a couple years back. We obtained our original print from The Spore Works. After our grower, -Clyde- at the Birds Nest, grew it out several times, he really enjoyed it and decided it was a keeper. Its a semi fast grower and produces some large caps. We've heard a lot of ppl give praise to its potency and heard from several different circle of friends they find the green and purple spectrums of sight are very enhanced.
An additional note to avoid confusion. Another popular spore supplier claims the PES Hawaiian and Golden Teacher (GT) are one and the same and sells them this way. -Clyde- has grown them both out several times and found they were completely different in size and growth, and decided the PES H was not worth keeping (in our opinion, if you enjoy it then great!)and the GT is definitely worth keeping and spreading the seed. Enough said, we're going with the GT.

Psilocybe cubensis „Guadalajara mexico“

Another cubie from Mexico we're offering is this decent little strain of cubensis from Guadalajara. We're not exactly sure who the found the original specimen, but Workman found the connection in Mexico and fruited this strain to help spread the spores. Nothing really spectacular about its growing parameters. Semi-fast colonizer, produces rather small caps, but average in size overall. We decided to keep it for a while because the word around the camp fire is the potency is considered high for a cubie, and ppl have been asking for it. We have also noticed that most cubs from Mexico tend to be smaller then average, but also very visual. An additional note, its been in this authors experiences, that mushrooms from Mexico tend to deliver powerful spiritual journeys.

Psilocybe cubensis „Gulf Coast“

Gulf Coast cubensis generally means it is a wild growing cubensis that grows along ocean bordering states such as Texas, Alabama, Florida, Georgia etc. Spores from one state can easily travel to the next through birds, farm animals, hurricanes etc... They adapt along the coastal states to the new growing conditions and take up habitat near the warm humid ocean islands. From what I hear.. most people are very satisfied with these GC strains because they are fast colonizers and produce some above average potency. We do hear a lot that some people have a hard time getting them to pin and fruit easily, while other GC strains fruit very easily. We have worked with a lot of different GC strain over the years people have sent us. With so many out their from the coastal states of the U.S.A. we decided to stick with ONE that a good friend of ours has grown over and over and produced excellent results. We compared his results to the strain we were working with and decided he had the best strain of GC cubensis we had seen yet. After our grower -Clyde- worked with it a few times, sure enough we saw some great results and decided to keep it and stop all further work with the other GC strains such as the Alabama GC below. It is believed this one originated from Texas but our friend was not 100% sure on that. So for reference we are calling it T.H.E. GC so as to not get confused with the many other GC strains floating around out there. This one is truly exceptional and we're glad to add it to The Hawks Eye collection of exceptional cubensis strains.
This GC strain does not seem as stubborn as some of the GC strains we have seen in the past. It fruits very easily in a range of temperature conditions from 60F to 90F. For best results we recommend keeping temps around 75F.

Psilocybe cubensis „Gulf Coast Alabama US“
This strain of cubensis was sent to us from a sacred mushroom hunter in Alabama U.S. We originally received the print, it was easily 6 1/2" in diameter. One very large print from a very large mushroom. The hunter said it was one of his favorite strains of cubensis he hunts there in Alabama, and judging from the print size and what we've seen when grown, we can see why.
This strain is a fast colonizer, and very easy to grow. Something unusual about it, was that the mushrooms grew in large clusters of 10-25 mushrooms. 80% of the casing grew this way. Overall, this GC Alabama is a real nice strain, but potency seemed rather low for a cubensis.
This Alabama GC strain fully colonized 1/2 pint finch seed/verm 2:1 ratio in about 16 days from inoculation. Started fruiting within 2 weeks of being cased, using 50/50+ tek. Tends to grow some very thick solid stems and grows in clusters. Grows well in temps ranging from 60F-85F. Not a real heavy spore depositor though, but a very fast growing mushroom.
A nice cluster of GCA's - 23 mushrooms in this cluster.

Psilocybe cubensis „Huautla“

Psilocybe cubensis strain finds its origins in Huautla de Jímenez, a small village in the Oaxaca state of Mexico. Here Gordon R. Wasson first tried *Psilocybe* mushrooms becoming the first white person to have experienced a magic mushroom ceremony.
This is the magic mushroom that Maria Sabina used for her veladas, when the *Psilocybe caerulescens* season was finished. It carries with it a spiritual load unequaled in *Psilocybe cubensis*.
Club99 collected this *Psilocybe cubensis* strain in the end of July, 2001 growing on a pasture land, into the grass. Interestingly *Psilocybe cubensis* Huautla was not seen growing directly on dung.
Magic mushrooms are tall and thin and have a uniquely shaped cap. *Psilocybe cubensis* Huautla is a easy fruiter.

Psilocybe cubensis „John Allen“

The following info about this strain was posted by John Allen at the entheogen.com forum!
The Allen strain was developed by Hydorogen of the Shroomery in honor of my research and spore print gathering.
Another one he developed was the Elephant Gate Strain. I did not name either one of those although they are from Koh Samui. The Allen strain I cannot recall what area it is from. I did not name it. But I understand it too is a fast colonizer like the BHT and the Cambodian Cubes.

Psilocybe cubensis „Keepers Creeper“

This mushroom arrived us by The Little Guy. We won a print in a nice contest on the Shroomery. So our first genetic material came from BoxTop from TLG and was won in a contest.The original Creeper comes from Keeper. Also an resource for prints, however the most expensive one on this globe. Personally I do not believe in his fantasie stock with fantasie hybrides and exclusive prices.

Psilocybe cubensis „Malabar“

Wonderful Prolific fruiter. Nice thick and meaty fruits. These can get fairly large. Unique cap that appears flat on top before the cap opens up. Stems are fairly thick, definitely dense, and meaty. Also veil tends to stay attached, sometimes even at full maturity. You will most likely have to break the veil yourself to print these. Avg. to dark spore depositor.

Psilocybe cubensis „Matias Romero“

This is a nice rizomorphic strain. Lots of pins and lots of aborts. But with proper moisture content and humidity many (but not all) aborts can be avoided. This strain loves water but don't go drowning it! Fat meaty stems particularly at the base of the stem and great yields. This strain is named after the Mexican village Matias Romero where it was collected. It produces, some smaller, but fat stemmed mushrooms that usually form in clusters. This strain profits a lot from cold-shocking. The veil for the most part breaks cleanly away from the cap and caps leave heavy spore deposits.

Psilocybe cubensis „Mazatapec Mexicana“

Another fantastic cubensis from Mexico is the strain picked around Mazatapec Mexico. For those of you into the spiritual side of mushrooms, I'm sure you will enjoy this one a lot, as I've always noticed mushrooms from Mexico tend to deliver a very powerful spiritual journey. We've heard a lot of great feedback from ppl over time on this one having very beautiful visions after embracing its gift. Although you may have a tremendous spiritual or visual experience on these, you'll need a little patience. These tend to colonize a little slower them most. Count on an extra 10-14 days to your project. The little extra wait is well worth it.

Psilocybe cubensis „McKennaii“

The first appearance of this strain was in Dutch smartshops. It was available as a fresh mushroom shortly after the dead of Terrence McKenna. We belief this strain was named after Terrence McKenna in order to honor him. This could be a marketing trick from the smartshops, but still it's very honorable to name a strain after Terrence Mckenna.
The following info is according to the website of one of our sponsors, which offers this strain as a Growkit:
"The McKennaii might be even stronger than the popular but difficult to grow Hawaiian (Copelandia cyanescens). No doubt the McKennaii is the strongest cubensis in our catalog. This one is for the more visually interested. Dark brown caps with an odd shape and thick sturdy stems."
Also this info could be part of the marketing trick!

Psilocybe cubensis „Mexican“

This mushroom was originally found in Southern Mexico, from Mr. G. A very beautiful mushroom always giving beautiful spotted caps, usually of a nice yellowish color instead of your typical cubensis golden tan color. Sometimes it even throws off some orangeish colored spotted caps. It tends to grow with smaller stems and rather large caps compared to its stem. A rather fast strain, and very easy to grow. It does exceptionally well cased, and will continue to flush over and over within a week of each other. Although not a giant sized mushroom, it produces an abundance of mushrooms continually. You can usually count on a minimum of 4 really good flushes from this strain, and sometimes more. Another nice key feature about this cubensis, as that it fruits well in cooler temps of 50F, but also grows like all other cubensis at the higher temps of 75F-85F.
One special characteristic about this mushrooms potency, is it doesn't seem to give the high anxiety a lot of mushrooms do when the first initial waves of euphoria come over you. Its a very smooth, clean high, with a nice heavy play on the eyes.
The mexi-cub is truly a beauty to marvel at for its unique appearance, definitely gets a "best of show" award.
Some beautiful new pics of the mexi-cub on Dung Brothers compost inside of the 10lb THE DB KIT. These are absolute monsters for the usually small growing mexi-cub.

Psilocybe cubensis „Mystery Fatass“

This strain produces mushrooms with the fattest asses you have ever seen! The caps are hard to print as she looses her spores poorly. The first flush consists of mushrooms with an unusually fat stem. In later flushes some very big mushrooms can be harvested.

Psilocybe cubensis „Nepal Chitwan“

Description: Original collection material was obtained by Baerbel near the Chitwan Jungle of Nepal. Three specimens were located in otherwise dry climate conditions, growing in tall grass and shaded by a nearby tree. Specimens picked from what appeared to be either elephant or rhino dung. Original sample specimen pictures below and right.

Macroscopic feat.:

Cap/Pileus: 20-70 mm in diameter, hemispheric expanding to nearly plane with age. Golden brown maturing to light brown. Fine fibrillose veil remnants when young that soon mostly disappear. Flesh yellowish white soon bruising bluish green.
Stem/Stipe: 150-200+ mm in length. Typically equal, sometimes slightly enlarged at base. Yellowish to buff with a reflective sheen, bruising bluish, semi hollow with remains of the partial veil.
Gills/Lamellae: Attachment adnate to adnexed. Yellowish coloration in young fruit bodies becoming darker in maturity. Remains of the partial veil attached at the outer circumference of the cap.

Microscopic feat.:

Basidio/Spores: Dark purplish brown, subellipsoid on 4-spored basidia.

Psilocybe cubensis „Orissa India“

All the way from India, an EXTREMELY large growing cubensis that spawned from elephant dung has blessed us all. This strain of cubensis has to be one of the largest growing anyone has seen. Originally brought to us my entheomycologist John Allen, once again a big thanks John, this one really rocks the boat. Ever seen dinner plate sized mushrooms? Even on simple rice cakes in Amsterdam this one grows some rather large mushrooms.
-Clyde- and his fellow Amsterdam growers have seen some mixed results from this one as well. Although something so large comes with a small price, at times its rather unstable when taken from the dung fields to the grow shops of Amsterdam. The Amsterdam growers tells us although the first flushes at times can be unstable, the rest are outstanding and produce these monster mushrooms like they have never seen. The Indian cubensis also grows around most green mold like its nothing. They continue to flourish around green mold like Oyster mushrooms do. I guess it must be something in the elephant dung that has helped this mushroom develop and immunity to most green mold (trichoderma) The more -Clyde- has worked with it the better it gets.
Colonizing speed is average, potency is extreme for a cub from the feedback we got from the Amsterdam coffee shops and the locals in India.

This strain is worth a try!!

Psilocybe cubensis „PESA“

Ready for some drama and controversy :). This one has an interesting story behind it. A company out of Hawaii called Pacific Exotic Spora (PES) advertise this strain as a cubensis/azurescens hybrid. They even went so far as to claim it came from the mushroom master Paul Stamets himself. Well people, there has been a lot of azure/cub hybrid scams in the past, and to this day the experts such as P. Stamets have not published any information about being able to hybridize a *Psilocybe azurescens* with a *Psilocybe cubensis*. They are completely different species and this task would certainly be extremely difficult. I'm sure if anyone can do it, P. Stamets can, and hopefully one day he will. But until something is published, do not buy into it. This is nothing more then a very potent cubensis.

About a year ago when they started advertising this hybrid, a bunch of us pitched in to get a print of this (yes, that is how high there prices are :) and Workman grew it out and once again, a cub/azure hybrid was nothing more then a cubensis. Our grower here at T.H.E. has grown out all the cubs from PES, and found this the only one worth keeping. Another company, PF, sells the PES Hawaiian, which is a different strain, and some ppl have the PES Amazonian, this strain is neither of those. If it helps with any of the confusion, just call it PESA.. and the A does not stand for Amazonian. I think it originally stood for Azurescens.
PES (Pacific Exotic Spora)has been around for a while, and sells quite a few strains of cubs and panaeolus at a very very high price. We normally will not carry other strains that is unique to one company. But, since PES charges such a ridiculous price for a print of this strain, we decided to go ahead and carry it and share with everyone because most ppl will enjoy the extreme potency.

Ok, enough of the controversial babble, now lets get down to the fact of this strain. Our grower -Clyde- finds this to be one of the most bluing cubensis he has ever worked with. After cutting these with a blade, they turn dark blue within 2-3 seconds!! Most cubs, take about 10-20 seconds to start turning dark blue. And everyone we know that has tried them found them to be extremely potent as well. Perhaps this is why PES started calling them cub/azure hybrids since the *Psilocybe azurescens* is the most potent mushroom in the world.
So yes, the PESA is a VERY potent cub, but potency is not everything. It produces some very light caps, although large caps compared to small stems, and does tend to abort a lot. As you will see in the pics below if you look real close. It is a semi-fast colonizer, and fruits nicely in cold temps. So this mushroom does not utilize all of the substrate very well, but the mushrooms it does produce are just extremely potent and its a real good strain to add to your collection. Like I said, it was the only one of the PES strains we liked enough to keep. And its one of our growers favorite strains, I think he is just impressed with the extreme speed of the bluing effect... so easily entertained (wink).

Psilocybe cubensis „Penis Envy“

We're happy to finally be able to bring you spores of our favorite cubensis. We would have loved to brought this one out sooner but this mushroom is extremely hard to obtain spores from. Only about 10% of the mushrooms actually drop spores. Every time we had a few prints they sold out immediately!

Why is that? Well it is a mutant mushroom in a sense. This one was developed by the famous entheogenic mycologist/enthobotanist and psilonaut Terence McKenna, God bless his resting spirit. For those not familiar with Terence McKenna he was a famous author, speaker, mycologist, botanist on psychoactive plants and fungi. You can find a whole vault of his teachings in MP3 format at this link.

My personal favorite book by him is Food of the Gods. Unfortunately Terence McKenna died last year of a brain tumor and now resides in Gods hands :0) See you on the cosmo highway Terence.

Besides his wonderful teachings he left behind to fuel our thoughts and imagination, he also left one of the most unique and powerful cubensis mushrooms we have every experienced. Its nick named Penis Envy because they resemble.....well......you guessed it.. a penis. Terence was big on mushrooms and marijuana and he talks a lot of psilocybin mushrooms being a "male" energy and mj being a "female" energy. No wonder he developed a mushroom that looks like a penis :) Listen to many of his teachings and you will hear what I'm talking about.

OK now for some information on the mushroom itself. Well this one is straight up amazing. Its favored by many and yet feared by others. Why? Its very powerful medicine. Most of our friends in Amsterdam claim this one is twice as strong as any cubensis they have ever tried. The vibe lasts a long, long time. It does not come on in "waves" as most cubensis do. Its a solid ride from start to finish. Once your on the vibe its solid.. it keeps going strong for many many hours... but in a very beautiful way. A few friends claimed it was to strong but most wanted more, more, more! On the times I had the opportunity while outside the U.S. to eat these, I was mesmerized. It was the perfect vibe for cubensis in my experiences. I love the fact it doesn't hit you in waves. Its the same strong vibe throughout the experience. It is very smooth, and clean and easy on the body. I always felt like a million bucks the day after eating these. In my humble opinion, this is the perfect vibe from a cubensis!

Provided you live in a country where its legal to grow and eat psilocybin mushrooms, treat it like any other cubensis. You will not get huge flushes from it, but what you will get are extremely solid mushrooms that are the thickest cubensis mushrooms every seen. They are like little wood logs, solid all the way through. Once dry they weigh a lot more then appears. In fact eating them, its best not to just chomp down a mushroom unless your ready for an intense experience. Its best to break them up into a lot of pieces, almost fluff them up. What appears to be an average mushrooms fluffs up into a huge pile expanding to 3 to 4 times its actual size. Then you can judge your dosage much better. They grow very large on compost and dung based substrates as well on birdseed and rye grains. Our grower in Amsterdam has never grown them on rice cakes so no idea how they perform on that substrate.

Now although this mushroom really is amazing, it drops very limited spores. If you cant get any spores from your mushrooms you can always cut off a piece and use tissue culture techniques on agar, cloning. Or you can take a cotton swab, such as a Q-tip and rub in the gills real good to get some spores, then later drop that in a bag of grain or streak it across agar. Of course that assumes you live where its legal to grow. Because spores are so hard to obtain from this mushroom they are priced much higher. Also we can not give these out free with our combo deals unless you buy at least 3 spore syringes as well. Thanks for understanding.

A few pics for now. We have a lot more but they are all on video tape and I don't have time right now to pull them off. I will hopefully post some more amazing pictures soon. In fact I have some video footage of these already edited and will hopefully post that soon as well. I promise I will get some amazing pics up before we go out of business.

The mushrooms from these pictures are average in size. But even the largest mushrooms in these pictures will dry to almost a 1/2 oz. That is how dense they are! -Clyde- started these on rye grain then transferred them to 10 lbs of compost. Just from one flush like this they will dry to about 3 ounces! Pretty damn amazing. As long as you can get over eating a mushroom that looks like a dick you will have many happy experiences on these.

Psilocybe cubensis „Penis Envy 6“

Shroomery veteran RogerRabbit, "Crossed a standard PE with the Tex strain." The result was PE 6.
RogerRabbit's efforts were an attempt to create a PE strain which produced more spores... but the spores were accidentally released too early... when a few prints were unintentionally mailed out, in a stack of other prints.
Here's how RogerRabbit says PE 6 came to be.

"A single sector fruiting isolate of PE, and another of TEX were placed on a Petri dish with rattlesnake venom added to the agar. The snake venom helped the two dikaryotic strains share genetic information to form a third sector, which was which was labeled PE6. Other Isolates of the PE were labeled PE 1-7, and apparently, some of the 6, which was the cross, were in the same batch of prints. The idea was to get a good spore producing PE, but I never had time to stabilize the strain due to accidentally releasing it early. That's why sometimes they look like texans and sometimes very much like PE."

PE 6 looks like a cross between Penis envy and Texans. The fruits often have LARGE caps, which open fully, unlike classic PE. They also produce spores. While the stems look quite a bit like PE. Thick and textured. Like little logs.
RogerRabbit confirms this description: "the caps that opened fully have fewer spores like PE, and they have the same gnarly stems too. Only the caps seem to be bigger and to open all the way."

Psilocybe cubensis „PF Classic“

This PF strain is no different strain that the normal PF Classic. However this strain has been cultivated from approx. 1990 only on PF cakes (brf/verm) with no interruption of tissue culture.
In order to keep this strain clean we hope you only use them on brf/verm cakes as the PF style describes. Classic 90 prints are a kind of collectors items I think and that's how they are offered. In order to keep this strain 100% real we will place the returned 90 prints in the regular Classic stock.
This strain was donated by René of Perfect Fungi Europe. This strain is 100% Robert McPherson original. So it is the one and only PF Classic from the one and only Mister PF.

Psilocybe cubensis „Plantasia Mystery“

We're very happy to be able to bring this strain to you. There were a lot of rumors surrounding this strain for quite some time back in 98. It originated from The Grow Room, but Plantasia is no longer in the spore business so we asked him if he minded if we sell his unique strain and he was cool with it, so here is a new strain that we at The Hawks Eye think is good enough to turn everybody on to. Originally it was unsure weather this strain was an azurescens or cubensis. As you can see from some of the outdoor pics, it looks a lot like an azure, but it grows like a cubensis, it loves warm temperatures. Rumor has it this strain was being handed out by P. Stamets himself, as an azure, at a mushroom conference in Mexico some years back. And as you will see from some of the pics, they do look a lot like huge azurescens, but they are not.
Update December 2000. We're very happy to bring the Plantasia cub back again. This is one of this authors personal favorites for the experience they provide. They always seem to give me extremely happy thoughts and a huge smile across my face :) as well as those around me. Just a beautiful happy vibe.
As for growing, they are semi-fast colonizer, fruits are average in size, and very beautiful as you will see from the pics. This strain not only does well in heat, but also in cooler temps outdoors. Enjoy.

Psilocybe cubensis „South American“

Macroscopic feat.:

Cap/Pileus: 25-125+ mm in diameter, hemispheric to convex to nearly plane at maturity. Dark red maturing to golden brown. Fine fibrillose veil remnants when young that soon disappear. Flesh white soon bruising bluish green.
Gills/Lamellae: Attachment adnate to adnexed. Grayish coloration in young fruit bodies becoming nearly black in maturity.
Stem/Stipe: 150-350+ mm in length. Typically equal, sometimes slightly enlarged at base, sometimes contorted. Yellowish to buff with a reflective sheen, bruising bluish, hollow. Partial veil membranous leaving a persistent membranous annulus that is well dusted with purplish brown spores even before tearing away from the cap.

Microscopic feat.:

Basidio/Spores: Dark purplish brown, subellipsoid, 13 by 8 micrometers on 4-spored basidia.

Discussion: Produces some very large mushrooms, and a very heavy spore depositor.
This strain is a great all around performer! Fast growth and high yielding clusters in the wild. You'll get some monsters from time to time with this strain. Rizomorphic mycelium eager to spread and caps tend to split some and this to be due to the fast growth rate of the fruits. Heavy spore depositor.

A favorite among many! The spores of this strain can produce one of the fastest growing cubensis out there. High yields, big fruits, an all around winner.

This strain comes from South America. Quick colonizer that produces mediums sized fruits. One not to miss in any true collector's library.
The South American strain was originally sold by Spore Chicks from a strain collected in Venezuela.
It tends to colonize very quickly with a dense pinset.

Syzygy was the name of a Spore vendor back in the early days. The person behind this company was apparent Terence McKenna. Below is a copy of there advertisement in the book "Psilocybin: Magic Mushrooms Grower's Guide" by Oss & Oeric.

A 25year old spore print originating from this company was reincarnated and these spores now circulate under the name "Syzygy". This strain was first donated to the FSRE by Anand.

Psilocybe cubensis „Tasmanian“

The Tasmanian cubensis is a fantastic mushroom found by BIO on the island of Tasmania just below Australia. Tasmania is a state of Australia, sub-tropical, having 4 seasons. It tends to get very cold their at times, and as -Clyde- found out, this mushroom does very well in cold temperatures outdoors, Our grower -Clyde- did some work with the Tazmanian cubensis and was just ecstatic about this strain of cubensis. He says its extremely fast growing on compost, high yielding, and produces some very large capped beauties as you will see in the pictures. He also gave word people will be very pleased with the sensation within it provides. Not much more to tell on this one yet, its new to us and we haven't seen much talk about it yet on any message boards. -Clyde- thinks people are going to be talking very highly of this strain once it gets around.

-Clyde- says this is an extremely fast grower. At 80F temps, it colonized 10 lbs of compost in 5 days !! That is very fast. Most other fast strains he says does it in around 10 days. Unfortunately, we only have one picture of it indoors, but what a nice picture it is.
This is a close up, with a film canister for size comparison.

Our grower had some fun with the strain outdoors. After the trays of compost started colonizing, the trays were put outdoors in cold temps. The average temp range was a hi of 75F, and a low of 45F. The Tasmania cub still colonized fast, and produces some very beautiful yellowish color cubs.
Another characteristic our grower likes about the Tasmania cub is its a real good 2nd flush producer. This same outdoor tray above, produced a nice abundance of large capped mushrooms on the 2nd flush as well.

Psilocybe cubensis „Teonanacatl“

This strain was observed and collected for the 1st time by Mauritius (founder of the pro-fungi, Brasil) in the Lowland region Careiro, state of Amazonas, Brazil.
During the rainy season extending from September to May, buffalo breeders bring their pets to farms flooded by the road BR 319 that connects the Careiro Varzea Careiro to Brown. With the end of the rains the animals are transported to other areas. In July of 2008 Mauritius entered a farm and collected a mushroom of the genus *Psilocybe cubensis* from the buffalo manure.
The spores of this strain where clean on agar and sectors of mycelium where isolated for 1 year to select the best growing mycelium on rice and corn.
The name is in reference to the site Teonanacatl.

Psilocybe cubensis „Thai“

This strain is sold commercially in the smartshops in The Netherlands as "Thai cubensis". A very nice strain to grow, although the mushrooms themselves are not that big, the huge first flushes make up for this. This strain produces very well and easy. No cold-shocking is required.
The picture show a some very mature first flush mushrooms grown on sterilised rye cased with peat/lime.

Psilocybe cubensis „Thai Pink Buffalo KS“

This particular strain also comes from the beautiful island of Koh Samui, Thailand and was brought to us John Allen. What makes this one so unusual is that it was found in a field that was inhabited by one of the sacred pink buffalo of the island.
Like the other Thai strains, this one is considered one of the more potent strains of the *Psilocybe cubensis* variety. It's worth mentioning that these Thai strains are very fast colonizers and tend to produce larger fruitbodies in later flushes rather than the initial ones. Another great strain from Ban Hua Thanon - Koh Samui, Thailand.

Psilocybe cubensis „Thailand Ban Hua Thanon“

The scientific name is Ban Hua Thanon, after the island it was first found on. Our Ban Hua Thai is very very easy to cultivate, totally white and looks like an albino - shroom ;)
While it grows in the same standard temperatures as other members of the PC genus, it has also been known to colonize at as high as 30 degrees Celsius.
This Mushroom is probably the most beautiful we have to offer!

Psilocybe cubensis „Thailand Lipa Yai“

Another great psilocybe mushroom brought to us by Enthomycologist John Allen from his travels through Thailand. This fantastic species of cubensis was picked in this field in Lipa Yai on the island of Koh Samui, Thailand. And this big beautiful buffalo is one of the benefactors that helps these wonderful mushrooms flourish all over Thailand :) A huge thanks again to John Allen, a.k.a. Mushroom John for taking the time to seek out these mushrooms on his travels and bringing back spore prints.
This strain of cubensis from Thailand is a another winner. We were hesitant to make available 2 strains from Thailand thinking they might just be the same strain of cubensis that migrated. After growing both strains, the Koh Samui and the Lipa Yai out several times they clearly show many differences and traits and are both exceptional strains of mushrooms worth spreading.
The Lipa Yai strain is similar to the Koh Samui strain in the fact it is a fast colonizer, is a strong resister to contamination, fruits very easy and fast, and is very potent for a cubensis. The big difference in the 2 is that the Lipa Yai grows taller and produces a lighter cap. The Koh Samui tends to produce smaller, yet very thick stemmed and large caps, while the Lipa Yai grows taller, semi-thick stems, and semi-large cap. Both are excellent strains. The feedback we've received from those who have sampled its spiritual gift, absolutely love this one. Very potent!!! It's no wonder why in Thailand they have the full moon festival every month where thousands gather to eat these sacred mushrooms and experience God-Within together. Looks like its time for a TRIP to Thailand :)

Psilocybe cubensis „Thailand Koh Samui“

Another great psilocybe mushroom brought to us by Enthomycologist John Allen from his travels through Thailand. This beauty was picked in the town of Hua Thanon on the island of Koh Samui. Here is a picture of the field actual field it was picked in.

A huge thanks again to John Allen, a.k.a. Mushroom John for taking the time to seek out these mushrooms on his travels and bringing back spore prints.
This strain of cubensis from Thailand is a real winner. Its very resistant to contams, is a very fast colonizing strain and the fastest fruiting strain of cubensis we have seen. It tends to grow some very **thick** mushrooms with large caps. Although they don't grow real tall, they make up for height in thickness. Some times it tends to grow some nearly shaped mushrooms, but we hear the stranger they grow the more potent they are with this strain :).
Its potency is phenomenal for a cubensis. We've heard nothing but great reports back from people that have experienced its gift. Many friends have claimed it to be the most potent cubensis they've tried yet, saying they are very "twisted", and asked for these specifically by name the next time they were ready to journey. You'll need to be the judge of that for yourself.Another group of friends have dubbed them "the cloud mushrooms" you'll see what I mean when you enjoy viewing the clouds on these.
It's no wonder why in Thailand they have the full moon festival every month where thousands gather to eat this sacred mushroom and experience God-Within together.

Psilocybe cubensis „Thailand KS Lamai Beach“

Another great psilocybe mushroom brought to us by Enthomycologist John Allen from his travels through Thailand in 2000. This beauty was picked and printed on Lamai Beach on the island of Koh Samui in Thailand. A huge thanks again to John Allen, a.k.a. Mushroom John for taking the time to seek out these mushrooms on his travels and bringing back spore prints.
This strain of cubensis from Thailand is another winner. Our grower -Clyde- had grown out all the strains from Thailand brought back these last couple of years and we only kept the best ones. After growing it out through several generations, this strains is acting more domesticated and producing some amazing flushes. Although at my discretion to have so many Thailand strains, -Clyde- insisted we spread the spores of this strain as it produces an abundance of mushrooms in a small surface growing area. Colonizing and fruiting speed is average, mushrooms are plentiful, and once again, as with all of our Thailand strains, this one is yet another very potent mushroom for a cubensis. We hope you enjoy it :)
All of the Thailand strains are quickly becoming The Hawks Eye favorite cubensis.

Psilocybe cubensis „Transkei“

This is a *Psilocybe cubensis* strain from South Africa. It was the first strain of *Psilocybe cubensis* in wide circulation that originated from the African continent. The original magic mushrooms were collected in January 2002 in Transkei, in the Wild Coast region of South Africa. The magic mushrooms were growing directly on dung in the shade of trees.
Psilocybe cubensis Transkei magic mushrooms are medium sized and have a pretty solid stem that's a little gnarled. Young magic mushrooms have bright orange/brown caps that later turn very pale to almost white. Combined with the purplish colour from sporulation, these caps take on a unique white/purple/golden pattern. The veil stays connected to the cap for a very long time until it tears, leaving remnants on the stem as well as on the cap. Most *Psilocybe cubensis* strains have a veil that tears from the cap and stays on the stem. Mycelium on agar grows very rhizomorphic.
Cultivation is pretty much the same as with other *Psilocybe cubensis* strains although the formation of overlay and stroma is to be expected. A cold shock does not seem to have any effect on this *Psilocybe cubensis* strain. Overlay makes watering impossible but the wildly growing mycelium will act as a contamination barrier protecting the substrate. Still magic mushroom yields are substantial and certainly not bad for any *Psilocybe cubensis*. As magic mushrooms are pulled from the casing they open up the casing layer beneath making watering possible again. Magic mushrooms show extreme bluing when bruised.

Psilocybe cubensis „Tulum“

The variety Tulum, is not exactly a Mexican variety of psilocybe, the name came because the Collective SANTOVIAJE, spanish people of fungic and botanic speciallist with a biochemistry, and the help of a Mexican-Spanish shaman and friend, who stay for 1 year living in the state of Quintana Roo, Mexico in 1999, trying to make an hybrid... the varieties that was present in that "experiment" was: *Psilocybe baeocystis*, *Psilocybe cyanescens*, *Psilocybe mazateca* and *Psilocybe cubensis* strain Thai Pink Buffalo.
The result of that experience was a mushroom very potent, although not necessarily a hybrid, and ready for the weather and temperatures more colds like in Europe, and ready too for outdoor grow and little attention. They call the strain Tulum, because the culture grow there and after the strains came to Spain the culture #11 was the best. Initially few persons have the strain and then it spread via Holland...
Robust and resistant to contaminants. It grows well in Brown Rice. There are reports that under favorable conditions it can give very large fruits.

Psilocybe cubensis „White Treasure Coast“

Well, here it is, a white cubensis. Pretty isn't it? This white cubensis is a substrain of the Treasure Coast Cubensis from Florida. The Treasure Coast Cubensis was brought to us by the grower for the former FMF, that went by Mr. G. He has done some interesting breeding with the TC strain, and it will throw off 4 different substrains. One of them being this very unique white cubensis. We have seen a variety of substrains come from this strain, and most recently several casings of all white albino mushrooms. The white cubensis starts off a very light brown, then changes to the frosted white at about 1 1/2" to 2" tall as it matures. All the substrains of the TC will have a frost look on the caps with, and they are all very potent mushrooms, the white being more potent then the rest for some reason.

For a long time this mushroom strain has been considered slower then most. The problem was solved by dramatically increasing the spore count in the syringes. It also tends to be fast on rye grain and fast on straw. This one is a very beautiful mushrooms worth checking out.

Currently all spores being sold of the Treasure Coast Cubensis are from these white albino mushrooms. There is no guarantee you'll see the white substrain, but your chances are much higher from these spores.

Psilocybe cubensis „Wollongong“

This strain originates in the Illawarra escarpment near the city of Wollongong, Australia. The Illawarra escarpment is the mountain range west of a narrow coastal plain south of Sydney, enclosing the region known as the Illawarra which stretches from Stanwell Park in the north to Kiama, Gerringong and the Shoalhaven river in the south. The hills of the plateau reach over 400 m and may drop abruptly to the coast.

The Wollongong strain tends to be very aggressive. The pinset is very even. First and second flush fruits tend to be the largest. What's very remarkable about this strain is the color of the caps, which are a beautiful almond-like color. You can even see the edges of the caps have stripes. Very different from other strains.

source - www.fsre.nl

Psilocybe cubensis „Z-strain“

Some cultivators say is also the Golden Teacher, but is really it's own strain displaying different characteristics than the GT. An aggressive colonizer and prolific fruiter, the Z-strain produces medium to large fruits.

The original Z-Strain comes from SporeTradingPost for the grazy price of $90.00. This amount of money is way to much for a simple print. Personally I do not believe in his fantasie stock with fantasie hybrides and exclusive prices.

Most growers even speculate if the Z-strain is indeed a new kid in the mushroom three. It is extreme hard to make hybrides. And very doubtful that one guy produces all those hybrides. The are most likely renamed cubensis strains.

Psilocybe acutipilea

Psilocybe acutipilea (Speg.) Guzmán

---

synonyms:
Deconica acutipilea Speg. (1889)

Macroscopic feat.:

Cap/Pileus: 7-10 mm diam., globose-conic to conic-papillate, smooth to somewhat striate at the margin, hygrophanous(?), brown to brownish, viscid (?).
Gills/Lamellae: Subadnate or sinuate, brownish chocolate with whitish edges.
Stem/Stipe: 50 x 1-2 mm, cylindric, hollow, flexuosus, whitish to yellowish, covered by floccose white fibrils (it seems to stain blue when injured).
Context: Whitish.
Odor: And taste unknown.

Microscopic feat.:

Basidio/Spores: (7-) 8-9.5 (-11) x 5-6 (-7) x 4-5 µm, subrhomboid in face view, elliptic or subelliptic in side view, thick walled, brownish yellowish, with a broad basal germ pore.
Basidia: Basidia and pleurocystidia not observed (hymenium collapsed) (it is possible that there are no pleurocystidia).
Cheilocystidia: 15-28 x 5-8 µm, hyaline, abundant, vesiculose-pyriforme with long neck 8-10 x 1-2 µm, forming a more or less sterile band at the edge of the gill.
Subhymenium: And trama brownish yellowish with hyphae collapsed.
Epicutis: Subgelatinized with hyaline elongated hyphae.

Habitat: Solitary on humus in subtropical forests. Known only from the type locality.

Studied material: BRAZIL, Apiaí (Apiahy), Autumn 1881, Spegazzini 1536 (LPS 38307 type).

Discussion: This species is close to *Psilocybe mexicana* Heim and *Psilocybe caerulescens* Murr., and seems to be intermediate between them. The size of the spores and the cheilocystidia serves to separate *Psilocybe acutipilea* from the other two species (see Guzmán 1977-B). It is possible that this species has hallucinogenic properties because of its relationship with those mentioned above that they are use by the Mexican Indians as psychotropic fungi.

Psilocybe aeruginosa

Psilocybe aeruginosa (Curtis) Noordel. (1995)

synonyms:
Agaricus aeruginosus Curtis 1786
Pratella aeruginosa (Curtis) Gray 1821
Stropharia aeruginosa (Curtis: Fries) Quelet (1872)
Stropharia alpina (M. Lange) M. Lange 1980

Macroscopic feat.:

Cap/Pileus: 2-8 cm broad, convex to campanulate, soon expanding to broadly convex, often with a low, broad umbo. Dark bluish green, sometimes fading with maturity. Surface viscid when wet and covered with a bluish green, separable gelatinous pellicle. Margin even, adorned with whitish flecks, remnants from the partial veil. Flesh thin, whitish, thicker towards center.
Gills/Lamellae: Adnately attached, broad, fawn to clay brown in color, sometimes tinged purplish, with white edges.
Stem/Stipe: 30-80 mm long by 3-12 mm thick, nearly concolorous with cap, equal, flared towards the apex, and swelled at the base. Surface covered with whitish patches. Partial veil membranous, leaving a fragile, membranous annulus on the superior regions of the stem, which is whitish above and bluish green below, sometimes disappearing in age.

Microscopic feat.:

Basidio/Spores: Dark vinaceous purple brown to purple black in deposit, 7.5-9 by 4.5-5 µm, ellipsoid, thick-walled with a central germ pore.
Cheilocystidia: lageniform-capitate and bluntly capitate, 40-55 by 10-12.5 µm.
Pleurocistidia: Mucronate, clavate, 40-60 by 10-15 µm.

Habitat: Widespread throughout the British Isles, northern Europe, and in western North America, on wood debris, in gardens, parks, and occasionally along grassy areas at the edge of woodlands. In the Pacific Northwest this mushroom grows beneath conifers and in the South-west under aspens. In southern California, it can be found under oak.

Comment: Activity suspected but not known. A spectacularly beautiful mushroom, *Psilocybe aeruginosa* is listed in most books as a *Stropharia*. Noordeloos (1995) proposed a new combination, placing this mushroom, more appropriately, into the genus *Psilocybe*, following the suggestions of Alexander Smith (1979). This mushroom has historically been reported as poisonous, perhaps because of its psilocybin content. (Some books still report it is poisonous, without providing elaboration or references.) Analyses of specimens from Washington found no psilocybin or psilocin (Beug and Bigwood 1982b). I know people who have eaten this species with no effects. In Europe, it is thought to be edible. Since the consumability of this species is questioned, caution is advised until the biochemistry of this species is studied further. See also *Psilocybe caerulea* (= Stropharia caerulea).

Psilocybe allenii

Psilocybe allenii Borov., Rockefeller & P.G.Werner (2012)

synonyms:
Psilocybe cyanofriscosa
Psilocybe cyanofranciscana nom. prov.

DESCRIPTION 1

Description: *Psilocybe allenii* was described as new to science in 2012 by Jan Borovička, Alan Rockefeller, and Peter G. Werner. Borovička received material collected from Seattle, Washington, which he noted was microscopically similar to *Psilocybe cyanescens*, but lacked the wavy cap margins characteristic of that species. In previous publications, Borovička had noted that both macro- and microscopic characters of certain *Psilocybe* species were highly variable, which could also account for the differences observed in the Seattle material. However, DNA sequencing revealed a 5-base pair change in the internal transcribed spacer regions (a segment of RNA often used in molecular phylogenetics to identify or distinguish fungal species) between *Psilocybe cyanescens* and the Seattle collections. This difference, in addition to the readily observable macroscopic differences, was deemed sufficient to warrant describing the taxon as a new species. Additional molecular studies published by Borovička and colleagues in 2015 identified *Psilocybe azurescens*, *Psilocybe cyanescens*, *Psilocybe weraroa*, *Psilocybe cubensis*, and *Psilocybe serbica* as closely related to *Psilocybe allenii*.
For several years before its official description, the taxon was known in the San Francisco Bay Area, and suspected of being an undescribed species. The authors suggest that a color photograph of "*Psilocybe cyanescens*" in David Arora's popular 1986 guidebook Mushrooms Demystified may actually depict *Psilocybe allenii*. Mycologist Paul Stamets suggested in 2005 that it "probably is new, or least a newly imported species". It is commonly called "Psilocybe cyanofriscosa" in the online mycological community, but this name is grammatically incorrect Latin and has never been validly published in scientific literature. The specific epithet allenii honors John W. Allen, who collected the original material and provided the impetus for the study. Allen collected the type material from the University of Washington Campus in November of 2009. He first collected the fungus in Capitol Hill in 1982, and several times later from Seattle. Some of these collections he sent to Mexican Psilocybe specialist Gastón Guzmán, who initially thought them to be *Psilocybe cyanescens* because of their overlapping spore size ranges. Fruitbodies of *Psilocybe allenii* are variable in size, depending on the substrate in which they grow.

Macroscopic feat.:

Cap/Pileus: 1.5-9 cm (0.6-3.5 in) in diameter, and range from broadly convex to flattened, sometimes with a slight depression in the center. The cap margin is either straight and slightly curved inward, rarely slightly wavy, and sometimes has radial grooves in moist specimens. The surface is smooth, sticky when moist, with a gelatinous cap cuticle that can be peeled. Wet fruitbodies are so slippery that they are difficult to collect. Caps are hygrophanous, and so will change color depending on how moist they are. They are pale orange brown to caramel brown when moist, but dry to yellowish-buff.
Gills/Lamellae: Gills have an adnate to sinuate attachment to the stipe, and are initially cream to pale gray brown, but become dark purple as the spores mature.
Stem/Stipe: The cylindrical, hollow stipe typically measures 4-7 cm (1.6-2.8 in) long by 0.2-0.7 cm (0.1-0.3 in) thick, with the base slightly thicker. The top of the stipe is pruinose (covered with white powdery granules), while the base is connected to thick white rhizomorphs. The stipe surface is smooth to silky fibrillose (as if made of silky, slender fibers), and its color initially white before yellowing slightly in age. Mycelium at the base of the stipe is white or stained blue. All parts of the fruitbody stain blue if bruised or handled. Young specimens have a white partial veil that later disappears, or remains as a zone on the stipe that can be colored purplish brown by spores.
Odor: And taste of the mushroom is farinaceous-similar to freshly ground flour.

Microscopic feat.:

Basidio/Spores: Spore prints are dark brown, sometimes with violet shades. Spores are thick-walled with an apical pore, and elongated ellipsoid to equilateral in face view, and somewhat inequilateral in side view, typically measuring 12.0-12.6-13.1 by 6.8-7.1-7.4 µm.
Basidia: The basidia (spore-bearing cells) are cylindrical, four-spored with sterigmata up to 5.5 µm long, and have dimensions of 27-37 by 9-11 µm. Clamp connections are present in hyphae.
Cheilocystidia: Cheilocystidia (cystidia on the gill edge) are abundant. They are hyaline (translucent), thin-walled, and variably shaped, and range from narrow clubs to narrow flasks with a neck no longer than 8 µm; their dimensions are typically 20-30 by 6-8 µm.
Pleurocistidia: The pleurocystidia (found on the gill face) are common; they are broadly club-shaped but taper to a point (sometimes with a rounded tip at the end), and measure 25-35 by 9-14 µm.
Caulocystidia: Caulocystidia (found on the stipe) are also present, with variable shapes similar to the cheilo- and pleurocystidia.

Notes: The mushrooms are consumed for their psychoactive properties, and have a potency roughly similar to *Psilocybe*

cyanescens. Borovička and colleagues say they are "commonly sought out by some mushroom hunters" According to Rockefeller, "If you go to Golden Gate Park in December you will see hundreds of hippies looking at the wood chip landscaping for *Psilocybe cyanescens* and *Psilocybe allenii*."
Several *Psilocybe* species have an appearance roughly similar to *Psilocybe allenii*, but these can usually be distinguished by differences in morphology or distribution. The European species *Psilocybe serbica* var. *moravica* has a similar cap and stipe, but is generally more slender than *Psilocybe allenii*. The closely related *Psilocybe cyanescens* is indistinguishable by microscopic characteristics, but features a wavy cap in maturity, a longer fruiting season (from late September through April), and lacks a ring zone on the stipe often seen in *Psilocybe allenii*. *Psilocybe azurescens* has a broader cap, an umbo that may be broad or acute, a longer stipe up to 20 cm (7.9 in), and a growing season similar to that of *Psilocybe cyanescens*. The authors also note that the Australian *Psilocybe subaeruginosa* is similar (including three taxa that have since been synonymized: *Psilocybe australiana*, *Psilocybe eucalypta*, and *Psilocybe tasmaniana*) but suggest that further research is required to better understand the delimitation of this species complex.

Habitat: *Psilocybe allenii* is found in the northwestern North America, with a range extending from British Columbia south to Los Angeles, California. It is most common in areas up to 10 miles (16 km) from the Pacific coast, although it has been collected 100 miles (160 km) inland. Fruitbodies grow scattered, in groups, or (more rarely) in clusters, on woody debris, such as wood chips often used in landscaping. Favored substrates include hardwood mulches made of oak, eucalyptus, Douglas fir, and alder. Fruiting occurs in cold weather, generally from late September to January. The species can be readily cultivated on agar, grain spawn, and cellulosic material, including wood chips and sawdust.

DESCRIPTION 2

Macroscopic feat.:

Cap/Pileus: 2-4.5 cm broad, convex or bell shaped; margin striate; surface smooth, sticky when moist, hygrophanous, brown, hygrophanous fading to yellow-brown or buff; flesh thin, brittle in age, bruising blue.
Gills/Lamellae: Adnate to seceding, close when young, subdistant in age, pale cinnamon brown, becoming dark grey-brown, edges lighter than the faces, mottled from spores at maturity.
Stem/Stipe: 3-6 cm tall, 3-6 mm thick, equal to sometimes enlarged at the base, the latter with conspicuous thickened mycelium (rhizomorphs); surface white, smooth to silky, bruising blue; veil fibrillose, forming a superior, evanescent hairy, annular zone.

Microscopic feat.:

Basidio/Spores: Purple-brown to purple-gray or purple-black; Spores 9-13 x 6-9 µm, elliptical, smooth, with an apical pore.

Season: Much Like *Psilocybe cyanescens* they prefer the cold temperatures of fall and usually are found late September into December, and October through January in California.

Habitat: Much like *Psilocybe cyanescens* they like the mulch and wood chipped areas. "Being a bit south helps (Tacoma and south Washington)" (NeoSporen). They are largely seen in the San Francisco Bay area of California where they get their name from.

Blueing: Bruising when handled. Especially in the cap margin.

Dosage:

- Lvl. 1 - 0,4g
- Lvl. 2 - 0,8g
- Lvl. 3 - 1,3g
- Lvl. 4 - 2,1g
- Lvl. 5 - 2,8g

Notes: In the book Mycelium Running by Paul Statements it says "microscopically, they seem identical to *Psilocybe cyanescens*, leading me to believe that these are probably *Psilocybe cyanescens*, and that this species is simply highly variable in macromorphology".
This species has been very well documented by amateur mycologists, however it has not been officially described and thus has no scientifically accepted species name at this time.
The nic name "Cyanofriscosa" was coined by a member of the website www.Shroomery.org a couple years ago when other Bay Area hunters began finding them. Other common names have been used to describe this mushroom, such as the "Cyclone Psilocybe", coined by Paul Stamets due to an instance in which the mycelial pattern of an agar culture looked like a spiral.

Mating crosses between isolates of *Psilocybe semilanceata* and *Psilocybe alutacea* always produced negative pairings." Y. S. Chang, G. M. Gates and D. A. Notes: This species shares many macro and micromorphological characteristics with *Psilocybe semilanceata*, *Psilocybe alutacea* appears to be close to the blueing temperate dung loving species, It has been put into section Semilanceatae by Dr. Guzmán.

Habitat: Mycenoid, like *Psilocybe mexicana* without pseudorhiza. Solitary or in small groups, in clay or sandy soil, in meadows with horses, cattle, or Indian Brahman cattle (Bos), and or water buffalo (Bubalus), with leavening grasses, in subtropical humid regions, at 1000-1600 m altitude. In manured ground but not directly from manure.

Distribution: Currently known only from Antioquia in Colombia; Jalisco and Veracruz in Mexico, and Angkor Wat in Kampuchea (formerly Cambodia). Probably a pantropical species

Season: Monsoon rainy season from late May through October.

Dosage: Unknown.

Comment: Collected from three locations in the Angkor Wat Compound of Cambodia at Banteay Srei (Temple of the Women), 15 km south of Banteay Srei (rice paddie area) and at Banteay Kdei (Citadel of the Cell). This species macroscopically resembles *Psilocybe semilanceata* and *Psilocybe galindii*. *Psilocybe antioquensis* was first reported from Colombia and *Psilocybe galindii* from Mexico. Both species belong to the section Mexicanae, but differ in the microscopic features. The main feature of these three species is the pseudorhiza which is a subterranean prolongation of the stipe. For more data concerning this species, read John Allen's paper *Psilocybe antioquensis*.

Psilocybe aquamarina

Psilocybe aquamarina (Pegler) Guzmán

---

synonyms:
Stropharia aquamarina Pegler, Kew Bull 1977

The study of the holotype [Pegler 370 (K), from Africa: Kenya, Central Province, South Nyeri Distr., S side of Ml. Kenya, Castle Forest Station, near Thiba River, on soil] shows a fungus with spores (9-) 9.5-11 (-12) x 6.5-7 (-7.5) x (5-) 5.5-6 µm, subrhomboid in face view and subellipsoid in side view, without pleurocystidia, cheilocystidia (20-) 22.5-34 (-36) x 7-11 (-12) µm, fusoid ventricose or vesiculose submucronate and gelatinized pileus with hyaline hyphae 1.5-2.5 (-3) µm wide. The basidiomata (two) are of the same colour as in P. cubensis, with pileus convex subumbonate and stipe with an annulus persistent. Blue tones are seen in the annulus and in some parts of the stipe. Pegler (1977) related this species to P. aerugineomaculans Hóhnel, which differs in the size of the cheilocystidia, as well as in habitat. The absence of pleurocystidia places this fungus in the genus *Psilocybe*, and its annulus and possibly a blue reaction relate it to Sect. Stuntzii Guzmán.

Psilocybe thaizapoteca Guzmán, Karunar. i Ram.-Guill

Macroscopic feat.:

Cap/Pileus: 2.5-5 (6) cm broad. Conic to conic-campanulate at first, soon expanding to convex, broadly convex, and eventually plane in age, and variably with a sharp umbo. Silky white at first, then yellow toned, soon brownish to reddish brown, and adorned with white fibrillose veil remnants in the lower two thirds of the stem, yellowish brown, and whitish near the apex. Partial veil cortinate, white, and leaving a fragile annular zone on the stem, if at all, and soon disappearing.

Microscopic feat.:

Stem/Stipe: 80-180 mm long by 3-5 (6) mm thick. Equal, tough, flexuous, swelling towards the base, which is adorned with whitish mycelium. Reddish to blackish underneath the appressed, fibrillose whitish remnants in the lower two thirds, and pruinose above.

Microscopic feat.:

Basidio/Spores: Dark violaceous brown in deposit, ellipsoid, 9-12 (14) by 5-7 (9) µm.
Basidia: 4-spored.
Pleurocistidia: Absent, or close to gill edge, and then similar to cheilocystidia, 30-38 by 4-6 (8) µm.
Cheilocystidia: Lageniform or fusoid ventricose with an extended neck, 18-30 (36) by 4-7 µm, and 1.5-2.5 µm thick.

Habitat: Gregarious to scattered or near sphagnum bogs, in coniferous and deciduous woodlands, fruiting in September and October. Reported from the United States (Michigan and upper New York to Maine), as well as British Columbia and central to northern Europe (Great Britain, Czech Republic, Slovakia, Finland, France, Germany, Sweden, and Poland). Probably more widely distributed.

Comment: Possibly active. Høiland (1978) reported psilocybin activity from specimens collected in Norway. No other studies are known to me. This species has an overall resamblance to *Psilocybe washingtonensis*, *Psilocybe physaloides*, *Psilocybe inquilina*, and particularly to several Hypholomas, namely *Hypholomas dispersum* (=*Naematoloma dispersum*) and *Hypholomas udum* (=*Naematoloma udum*). Its fondness for sphagnum bogs makes that habitat target-specific.

Cheilocystidia: 15-32 by 4-8 µm, ventricose-rostrate, with a long flexuous neck up to 12 µm long, often forking.

Habitat: Common. Grows scattered to gregariously on soil rich in woody debris and litter beneath *Leptospermum* and *Dacrydium* and in pine (*Pinus radiata*). Reported only around Auckland, New Zealand.

Comment: Estimated to be moderately potent. No analyses are known to me. With the heavy export of lumber and raw logs from the pine plantations of New Zealand, this species has a direct gateway for spreading to many other temperate regions of the world. This species resembles many of the lignicolous Psilocybes. See also *Psilocybe makarorae*, *Psilocybe subaeruginosa*, *Psilocybe cyanescens*, *Psilocybe cyanofibrillosa*, and *Psilocybe bohemica*.

synonyms:
Psilocybe mexicana var. *longispora* Heim (1956)

Macroscopic feat.:

Cap/Pileus: (5-) 15-20 (-35) mm in diameter, obtuse or convex to campanulate, becoming expanded, striate, hygrophanous, yellowish-brown or yellow-gold in some young button forms not strongly browning. Only the Margin stains slightly blue-green when injured.
Gills/Lamellae: Adnate or adnexed, light violet-gray to dark violet-brown or chocolate-violet.
Stem/Stipe: (25-) 55-75 (-95) x (1.5) 3-4 (-5) mm, equal and thicker at the base, straight, staining blue-green when touched or with aging, with rhizomorphs at the base of the stipe.

Basidio/Spores: (10.4) 12-14 (-17) x (6-) 6.7-7.7 (-8.8) x 6-7.5 µm. Elongate-ellipsoid in face view. Blackish-violate.

Habitat: Gregarious in groups of fruiting bodies of 5-20 specimens, growing on soil with wood debris or on twigs or very rotten logs, rarely on pine cones, in open woods of Pinus hartwegii with abundant grasses at the 3200-4000 m of elevation.

Distribution: Known only from the high mountains of Central Mexico, such as Sierra Nevada (Rio Frio, Popocatépetl and Paso de Cortés), Nevado de Toluca and La Malinche, in the States of Mexico, Puebla and Tlaxcala.

Season: This fungus fruits from August through October.

Dosage: Unavailable.

Comment: This fungus is employed by the Mexican Indians of the Popocatépetl region, e.g. in the town San Pedro Nexapa. The younger generation of Indian children sell this mushroom to tourists along the wayside road to Popocatépetl and also in Huautla de Jiménez. Two popular Náhuatl names for this species are "niños" and "niñitos." The name *Psilocybe aztecorum* was given to the species by Roger Heim in that it historically bestows a place of honor as it refers the Aztec priests and their people who employ them ceremoniously. They were known to have used this species long before the Spanish and Portuguese came to the New World. The Language of the Mazatec is Náhuatl, the language of their ancestors; the Olmec's, the Toltec's and their conqueror's, the ancient Aztecs and their cast uncharted Empire. The names "niños" and "niñitos" are used by shaman's and others who participate in all night vigils and veladas, as little boys and little girls. When consumed in a healing and curing ceremony, certain rituals are performed and depending on one's illness or misfortune, the fungi are always eaten in pairs of two and are considered as male and/or female and are always consumed in pairs of two; one male and one female. It also depends on what species are available since each species possess different amounts of psilocin and psilocybin.

Psilocybe azurescens

Psilocybe azurescens Stamets & Gartz

Psilocybe azurescens is probably the most potent psilocybin producing species on earth. Spawn can be grown on rye or birdseed and transferred to sterilised woodchips. Room temperature is fine for growing out spawn. This fully colonised woodchip spawn can be used to inoculate woodchips in outdoor beds.

Another option is to use grain spawn to inoculate soaked cardboard. Soaked cardboard is a highly selective substrate which can be used without sterilisation or pasteurisation. When the cardboard is colonised it can also be used to inoculate outdoor beds. More colonised cardboard or woodchip spawn results in faster colonisation of the chips in the outdoor bed and increases the chance of success.

As a substrate for the outdoor beds freshly chipped wood and branches can be used. If pre-packaged wood chips are used it might be necessary to soak them in water for a couple of days before using them. The beds should be made in a shaded place and can be covered with a thin layer of casing soil. Grass planted on top of it helps to keep the moisture content high.

Beds should start to fruit in the Fall and at that time extra watering might be necessary to keep the moisture content of the bed high. The bed should never be allowed to dry out.

Psilocybe baeocystis

Psilocybe baeocystis Singer & A.H. Smith

Macroscopic feat.:

Cap/Pileus: 1.5 do 5.5 cm broad to olive. center convex to conic. translucent when moist, appears pleated towards bottom portion of cap. Often staining blue to blue-green when damaged.
Gills/Lamellae: Attached. Dark purple.
Stem/Stipe: 50-70 x 2-3 mm long. White creme to yellow top. Covered with white filaments.

Microscopic feat.:

Basidio/Spores: 10-13.2 x 6.2-7 µ. Purple gray.

Habitat: *Psilocybe baeocystis* was 1st discovered in Eugene, Oregon in 1945. Once considered rare, this species was a very common mushroom appearing in mulched garden beds under rhododendrons and rose bushes during the late 1970s and early 1980s, sometimes growing in amongst groupings of *Psilocybe stuntzii* in lawns and with *Psilocybe cyanescens* in alder mulched garden beds. Although this species grows abundantly some in lawns or grassy areas rich in humus or lignin and/or in alder wood chips and bark mulch, it is sometimes very hard to find.

Distribution: From Eugene, Oregon to Seattle, Washington, up to British Columbia, Canada. Once considered rare, it is now common.

Season: June to October in lawns. From late September through December and sometimes into January in mulched garden beds.

Dosage: 1 to 2 large mushroom specimens or from 2 to 4 small specimens.

Comment: A very potent species when fresh. Stains intensely blue when damaged. Loses much potency when drying.
In the mid to late 1960s, two young children, both six years old reportedly died after allegedly consuming *Psilocybe baeocystis*. However, photographs given to the author by the physcians involved in the subsequent attempted treatment and later death of these children, one in Washington and a second reported death in California, were identified by (John W. Allen) as *Psilocybe cyanescens*. In both incidents, entire families had also consumed these mushrooms and did not die. Because of this misidentification by the late Chicago mycologist Rolf Singer and Alexander H. Smith who noted the species in their 1958 monograph on the genus *Psilocybe*, numerous mushroom field guides for both edible and psilocybian mushrooms described it as a very dangerous and toxic mushroom which could cause death. Over the years, few authors have corrected this error in reporting the correct identification of the species as *Psilocybe cyanescens*.

Habitat: Gregarious on bare soil in a trail of the subtropical (or mesophytic) fores. Fruiting in November.

Studied material: BRAZIL, Sao Paulo State, Mpio. de Cananéia, Ilha do Cardoso, Col. Guzmán 22960, November 18, 1982 (SP-177707 type) (XAL-Isotype).

Discussion: The form of the pleurocystidia, as well as the abundance, and the irregular form of the cheilocystidia, as well as the southern locality, are the features that separates this variety from the type, which is know only from the State of Veracrus, Mexico (Guzmán, 1978; 1983). These fungi belong to the Section *Brunneocystidiatae* Guzmán, distinguished by their brown pleurocystidia. All of them seem to be hallucinogenic mushrooms.

This European species is closely related to North American *Psilocybe cyanescens* (which is also spreading throughout Europe). *Psilocybe cyanescens* cap is not translucent-striate when moist, its lamellae are adnexed or narrowly attached, the veil connecting the pileal margin with the stipe more distinct. Macroscopic feat.:

Cap/Pileus: 1-3 cm broad. Conic at first, soon convex and eventually campanulate. Surface smooth, viscid when moist, and translucent striate along the cap margin. Reddish brown to brown when moist, hygrophanous, fading to light brown upon drying, becoming bluish in age or where damaged.
Gills/Lamellae: Attachment adnate, brownish to purplish brown, with whitish margins.
Stem/Stipe: 35-80 mm long by 1-4 mm thick, equal to slightly swelling at the base, which is usually adorned with whitish fibrils and/or rhizomorphs. Bruising bluish where injured.

Microscopic feat.:

Basidio/Spores: Dark grayish violet in deposit, subrhomboid to subellipsoid, 5.5-7.7 by 4.2-5.5 µm.
Basidia: 4-spored
Pleurocistidia: 22-29 by 8.8-12 µm, fusoid-ventricose to sublageniform.
Cheilocystidia: 9.6-13 na 5-7.2 µm, lageniform.

Habitat: Gregarious on grassy soils (*Axonopus compresus*) in forest of *Araucaria brasiliana* and *Podocarpus*. Known only from Brazil, near Sao Paulo, in March at approximately 1500 meters. Not yet reported outside this type locality.

Comment: Apparently active, Guzmán (1983) first discovered *Psilocybe brasiliensis*, and lists it under the psilocybin-producing varieties because of the bluing reaction. The general shape is reminiscent of some of the temperate *Psilocybes* like *Psilocybe cyanofibrillosa*. Being a grassland species, this mushroom is likely to be widespread and is a good candidate for cultivation in tropical environments. I think if more Brazilians were aware of this species, its range of dominion would be better documented. See also *Psilocybe aztecorum*, *Psilocybe baeocystis*, and *Psilocybe mexicana*.

Habitat: Gregarious or cespitose on rotten wood in subtropical forests. Known hosts *Castanopsis acuminatissima* and *Nothofagus* spp. Reported from Papua New Guinea only. 500-2000 m a. s. l.

Studied material: PAPUA NEW GUINEA, Morobe district: Bulolo, Manki; 13. III. 1972, leg. HORAK (Holotype ZT, 27/212; isotype ENCB) - Bulolo, Heads Hump; 2. XI. 1971, leg. HORAK (ZT, 71/226).

Discussion: This fungus is closely related to the hallucinogenic and lignicolous *Psilocybe yungensis* SINGER & SMITH described from Bolivia (SINGES & SMITH, 1958) and reported also from Mexico (HEIM & WASSON, 1958); furthermore it is close to *Psilocybe mammillata* (Murill) SMITH, a native species from Jamaica (MURILL, 1918). *Psilocybe brunneocystidiata* a differs from the before mentioned two taxa in the brown pleurocystidia and in the well developed veil remnants forming the distinct subpersistent subannulus. Obvious relationships also can be traced to several species recently described by GUZMÁN (1977) from tropical forests in Mexico (*Psilocybe naematolomiformis*, *Psilocybe singerii*, *Psilocybe uxpanapensis* and *Psilocybe weldenii*). All these Mexican species have brown pleurocystidia but are separated from *Psilocybe brunneocystidiata* by different cheilocystidia. From the taxonomical point of view brown coloured pleurocystidia as observed in some tropical species are considered as a primitive character in *Psilocybe* (Guzmán 1977).

Basidia: 4-spored.
Cheilocystidia: And pleurocystidia 28-55 by 10-16 µm, 2-4 at the apex, clavate-mucronate to fusiform or slightly lageniform with acute apices.

Habitat: A litter mushroom, thriving in garden-like habitats or soils enriched with manure. Widely distributed, reported from the British Isles, Europe, and northwestern North America.

Comment: Possibly mildly active. No chemical analyses are known to this author. This species differs from its close relative, *Psilocybe aeruginosa*, in its rapidly discoloring cap, the paler gills, and the lack of veil-formed scales on the cap surface, and its generally smaller stature. In Europe *Psilocybe caerulea* is more common than *Psilocybe aeruginosa* (= Stropharia aeruginosa). See also *Psilocybe pseudocyanea* (= Stropharia pseudocyanea).

Habitat: On marshy ground or in grasslands outside the forests of *Araucaria* and *Podocarpus*, in pasture land, sometimes on dung. Known from Brazil and Uruguay.

Studied material: BRAZIL, State of Sao Paulo, near Campos de Jardao, March 8, 1971, 1600 m elevation, Guzmán 8877 (ENCB; SP). Guzmán 8916 (ENCB; SP). Santa María, 1936, Rick (PACA 15234, Type of *Stropharia siccipes* var. *lugubris* Rick). Sao Leopoldo, 1934, Rick (PACA 9362, as *Stropharia inucta*). Without locality: Rick (Herb. Bresadola 287; NY, as *Stropharia luteonitens*). URUGUAY, Maldonado, May 27, 1966, Singer B-4172 (BAFC Holotype).

Discussion: *Psilocybe caeruleoannulata* is close to *Psilocybe stuntzii* Guzmán & Ott and *Psilocybe uruguayensis* Sing. ex Guzmán, but differs in the shorter cheilocystidia (*Psilocybe stuntzii* has cheilocystidia 22-27.5 µm a *Psilocybe uruguayensis* 24.5-32 µm. This species was named by Singer in the herbarium BAFC based on the collection from Uruguay. Later the author of the present paper collected the same fungus in Brazil and found the species in the herbarium PACA as *Stropharia siccipes* Karst. var. *lugubris* Rick, a variety described in 1939 but not considered in Rick's later papers (1961); this material agrees well with the type of *Psilocybe caeruleoannulata*; the variety of Rick is considered synonymous. Bresadola confused *Psilocybe caeruleoannulata* with *Psilocybe luteonitens* (Vahl ex Fr.) Parker-Rhodes, as the author noted in one of Rick's collections (NY), identified by Bresadola as *Psilocybe luteonitens*, but this species has spores 15.4-18.7 (-20) x 11-13.2 x 9.9-11 µm.

Gills/Lamellae: Close. Light cinnamon to brown. light to dark in age. Edges white.
Stem/Stipe: 3.5 to 10 cm. Long. Creme colored. Hollow with fiberous hairs, veil falls off early in young stages.

Microscopic feat.:

Basidio/Spores: Ellipsoid. Sporeprint dark purplish brown in deposit.

Habitat: Gregarious to cespitose, rarely solitary and often in clusters and clumps. On disturbed grounds devoid of herbaceous plants. Prefers mudslides and orange brown soils.

Distribution: Alabama, Mexico, Venezuela and Brazil.

Season: Late spring and summer months.

Dosage: 1-7 fresh mushrooms.

Comment: Paul Stamets mentions in his field guide, "*Psilocybine Mushrooms of the World*" that R. Gordon Wasson first ate 13 pairs of this mushroom during his initial velada with Maria Sabina. However, it was actually seven pairs of mushrooms. Timothy Leary also consumed this mushroom in 1960 in Cuernavaca, Mexico. He was given 7 fresh specimens of Psilocybe caerulescens his friend and associate, anthropologist Frank Baron. This species was first discovered and identified from Huntsville, Alabama in 1924 by the mycologist Murrill and never seen in the United States of America until the early 1990s in Florida and Mississippi. Later in the late 1950s, R. Gordon Wasson and Roger Heim identified it as the Derumbe (Landslide) mushroom of the Mazatec Indians. It has been reported from Oaxaca, Mexico fruiting from sugar cane mulch and landslide areas along sugar cane roads. Many Identification guides list this species as occurring in the southeast states of Mississippi to Georgia and Florida.

Psilocybe caerulipes Peck

synonyms:
Agaricus caerulipes

Macroscopic feat.:

Cap/Pileus: 10-35 mm in diameter, brown with a sticky surface when moist, bluing where damaged.
Stem/Stipe: 30-60 mm, white to buff, brown at the base with an evanescent partial veil, bluing where damaged.

Habitat: Woodchips and beauty bark in man-made gardens in public places.

Distribution: Georgia to Massachusetts in the north and west to Ohio and north to Michigan and southern Ontario.

Season: Late May through August into September.

Comment: *Psilocybe caerulipes* is unique in that it is the only active *Psilocybe* native to the NE United States. It is a wide ranging species but uncommonly found. The Bethany strain reportedly fruits in both the spring and fall. In deciduous forests on hardwood slash and debris, plant matter, on or about decaying hardwood logs, birch, beech and maple. It is often overlooked as just another little brown mushroom, and although widely distributed, it is not found often. It is sometimes confused with the larger *Psilocybe ovoideocystidiata*.

Habitat: Gregarious or caespitose on rich organic or sandy soil, mixed with decaying plant debris, in tropical and subtropical forests. Known only from Puerto Rico.

Studied material: PUERTO RICO, Mun. Naguabo, Luquillo Mountains, trail from Río Icacos to Río Prieto Dam, 4 Oct 1999, *Laboy* (PR-5772) (CFMR). Discussion: Pegler (1983) considered collections of this species from Martinique to be Psilocybe caerulescens. However, even though Psilocybe caerulescens is a member of section *Cordisporae*, it lacks pleurocystidia and is easily separated from Psilocybe caribaea, which has abundant pleurocystidia.
Psilocybe caribaea is attractive because of its robust basidiomata, which occur in clusters. Its habit is reminiscent of *Psilocybe collybiodes* Singer & A.H. Smith, but that species has thin-walled ellipsoid basidiospores (Guzmán, 1983). Psilocybe caribaea is most phenetically similar to Psilocybe subtropicalis Guzmán, known from Mexico and Guatemala (Guzmán 1995). However Psilocybe caribaea can be separated from Psilocybe subtropicalis, because it possesses two types of pleuro- and cheilocystidia (recent observations on the holotype by Guzmána and Tapia).
One specimen, PR-6170, possesses slightly larger basidia 28-37 x 6-7 µm with 1, 2, 3 and 4 sterigmata and slightly longer pleurocystidia (13-) 15-24 (-26) µm. However, the differences observed in this collection appear to be reasonably expected morphological variations for Psilocybe caribaea.

Distribution: Chuxiong, Yunnan Province, China.

Habitat: Growing solitary to scattered and gregarious on cow dung or grassland where cattle have grazed in summer and early autumn.

Studied material: CHINA, Yunnan Province: Chuxiong City, Zixi Mountain, on cow dung, 25°01'05.5"N, 101°23'19.9"E, elevation 2237 m, 20 August 2009, *Tao Ma CX026* (IFRD414-010, holotype). CHINA, Yunnan Province: Chuxiong, Wuding County, near a reservoir at road side in Bailu Village, on soil of grassland where cattle have grazed, 25°39'25.6"N, 102°05'30.0"E, elevation 2523 m, 24 Sep 2012, *Xiao-Fei Lin WD007* (IFRD414-011)

Discussion: Etymology refers to the location Chuxiong, where the collections were found.
Psilocybe chuxiongensis is characterized by its subtropical habitat where it grows on dung. The pileus is smooth, buff-yellow to yellowish brown, hemispheric to hemispheric-convex without an umbo or papilla, lacks an annulus, while the context is yellowish both in the pileus and stipe. Bluing mainly occurs on the surface of the lamellae and stipe when bruising and drying, and mycelium

are blue in culture. Microscopically *Psilocybe chuxiongensis* has large ellipsoid, elongate-ellipsoid to subhexagonal basidiospores 13-16 x 8-10.5 x 7.5-10 µm with slightly thick to thick walls, and hyaline, broadly clavate or ventricose pleurocystidia with an obtuse to short rostrate apex.

Following the taxonomical concept of *Psilocybe* proposed by Singer (Singer, 1948, 1986, Singer & Smith 1958), *Psilocybe chuxiongensis* belongs to sect. *Caerulescentes* Singer because of its surface bluing fruit body and blue mycelium in culture. In this section, it is closely related to *Psilocybe cubensis* as it has similar basidiospores, basidiomata, pleurocystidia and cheilocystidia, as well as the same habitat, and they can be easily differentiated from other species by the color and form of basidiomata, large spores and the subtropical habitat on dung. The relationship with *Psilocybe cubensis* is strongly supported by phylogenetic analyses in all three datasets; they cluster together as a sister group and can be distinguished from other members with high statistical support values.

Guzmán (1983) introduced sect. *Cubensae* to accommodate *Psilocybe cubensis* and *Psilocybe subcubensis*, which is characterized by coprophilous or subcoprophilous habitat, bluing basidiomata, subhexagonal thick-walled (0.5-1 µm) basidiospores, and a well-developed annulus. These two species are very similar and differ in the size of the basidiospores. Morphologically *Psilocybe chuxiongensis* can be easily separated from *Psilocybe cubensis* and *Psilocybe subcubensis* by the absence of annulus and the hemispheric to hemispheric-convex pileus without an umbo or papilla. Furthermore, *Psilocybe cubensis* and *Psilocybe subcubensis* have a white context, ovoid, broadly ellipsoid to subhexagonal or hexagonal basidiospores in face view, smaller ventricose pleurocystidia and fusoid-ventricose to lageniform to tibiiform cheilocystidia (Singer & Smith 1958 Guzmán 1983, Noordeloos 1999, Bau & Sarentoya 2009).

Discussion: *Psilocybe columbiana* belongs to the *Psilocybe zapotecorum* group because of its spores and floccose stipe, but differs in the size of the spores and form of the cheilocystidia. It is a hallucinogenic species since it stains blue and has a farinaceous taste and odor.

Cap/Pileus: 1.0-2.5 cm broad, at first hemispheric, sometimes with a low umbo at the disc, becoming convex, broadly so in age; margin incurved, in age decurved to occasionally plane, fringed with evanescent whitish scales when young; surface glabrous, subviscid, translucent-striate when young and fresh, hygrophanous; color reddish-brown to dingy yellowish-brown, fading in age; context thin, colored like the cap, unchanging when cut or bruised.
Gills/Lamellae: Adnate, subdistant, relatively broad, pale grey when young, becoming grayish-brown, finally purple-brown.
Stem/Stipe: 1.5 - 5.0 cm long, 1.0-3.0 mm thick, equal, dry, straight to sometimes curved at the base; surface often squamulose when young, becoming fibrillose, whitish to dingy yellow-brown, not bruising blue; partial veil absent or if present, evanescent leaving fine scales on the young pileus and/or in a superior ring zone.

Microscopic feat.:

Basidio/Spores: 11-14 x 7-9 µm, ellipsoid, smooth; spore print purple-brown.

Habitat: Scattered to clustered on horse and cow dung; fruiting after rains during the winter months.

Dosage: Nonactive.

Comment: This small dung dweller is recognized by a sticky, reddish-brown to dull yellowish-brown cap which when young is edged with cottony white fibrils and is typically translucent-striate. Unlike most *Psilocybe species*, *Psilocybe coprophila* does not bruise or discolor blue, with the exception of a few reports of bluing mycelium. *Psilocybe coprophila* does not bruise or discolor blue, with the exception of a few reports of bluing mycelium. *Psilocybe coprophila* is most likely to be confused with *Stropharia semiglobata*, another dung dweller with a viscid cap, but the latter is more yellowish, lacks a translucent striate margin even when young, and has a slimy, not dry stipe. Other mushrooms found on dung include *Panaeolus* and *Coprinus* species. Species of *Panaeolus* can be separated by dry, not viscid caps and distinctive mottled gills, while Coprinus species typically dissolve into an inky liquid in age.

synonyms:
Geophila crobula (Fr.) Kuhner i Romagnesi
Psilocybe inquilina var. *crobulus* (Fr.) Høiland

Macroscopic feat.:

Cap/Pileus: 0.4-4 cm broad. Convex to broadly convex, expanding to nearly plane with maturity. Dingy brown, hygrophanous, fading to yellowish brown. Surface smooth, translucent-striate, viscid when wet from a separable, gelatinous pellicle. Often adorned with fragile remnants of a veil, soon disappearing.
Gills/Lamellae: Attachment adnate, clay to dull rust, with whitish edges.
Stem/Stipe: 5-12 mm long by 1-4 mm thick, adorned with distinct fibrillose patches, concolorous with cap, more dark reddish brown near the base and lighter above an annular zone. Partial veil cortinate.

Microscopic feat.:

Basidio/Spores: Subellipsoid, thin walled, cigar brown in mass, 6-8 by 3.5-5 µm.
Pleurocistidia: Absent.
Cheilocystidia: Lageniform to sublageniform, 25-45 µm long.

Habitat: Fruiting in the fall on twigs and other wood debris - not on grass. Reported from the northwestern United States, Great Britain, much of Europe, and Russia. Probably more widely distributed.

Comment: Not known to me as being a psilocybin mushroom. However, Phillips (1981) notes that it is active, without further elaboration or supporting references. Analyses by Høiland's (1978) failed to detect any psilocybin or psilocin. *Psilocybe crobula* is a small mushroom, which I have always found directly attached to sticks. The fibrillose patches on the stem are quite distinctive, and reminiscent of many small Galerinas. For this reason, I urge caution. See also *Psilocybe inquilina*, a species similar in its macroscopic features and with which it is often confused, *Psilocybe atrobrunnea* and *Psilocybe washingtonensis*. Guzmán and Smith (1978) noted the similarities *Psilocybe crobula* shares with *Psilocybe laticystis* and *Psilocybe subborealis*, two species from the Pacific Northwest.

Psilocybe cyanescens

Psilocybe cyanescens Wakefield

We had the opportunity to visit Washington State and see some beautiful mushrooms in the wild. It was a very interesting adventure and very rewarding as well as educational. We had a great tour guide, John Allen a.k.a. mjshroomer, who has been picking mushrooms in WA for over 20 years. On the first day of hunting, our first stop was a church, where the sacred mushroom was growing on sacred grounds, I knew it was going to be a good day and a nice mushroom vibe after that. We found these growing amongts the alder mulch around the church. These pics can give you some idea of the surrounding these mushrooms grow in. Amongts all the alder mulch, leaves, twigs, etc. a nice little patch growing amongts some leaves, alder mulch and rhododendron bushes.

The next patch we found was growing amongts some large shrubs in the alder mulch. I doubt anybody would have known these were there if it had not been for John's resourcefullness of walking for hours a day looking in places ppl wouln't think of. We literally had to walk amongts some waste high bushes and move them aside to see them growing down underneith the bushes. These were the largest in size that we found of all the patches, they ranged from 4" to 6" in height, and had caps about 2-3" in diameter.

Well.. here is where the disappointment begins. Many of the patches we went to after this, during all the excitement I forgot to take pictures and even bring my camera. Yep.. I dropped the ball on that one. Thats ok.. gives me an excuse to go back to WA :)
One of the most interesting things I found, was that the deadly poisonous Galerina mushroom was growing right next to the *Psilocybe cyanescens* in almost every place we found them. What is even more frightening is they look pretty similiar. But dont let that scare you off from hunting them, you can tell them apart. And very distinctly upon a close inspection and taking your time to pick them. The *Psilocybe cyanescens* have a more caramel color cap, darker in color, and the stem of the *Psilocybe cyanescens* is always white, except around the base where the dirt is. Also the gills are much lighter and whiter in color then the galerinas. The galerina's always had a orangeish/brown color stem and veils, and the cap was orangeish brown as well. Once your out there picking them its easy to tell them apart if you have good eyesight and know what your looking for. If ever in doubt, also you can do a spore sample as the spores of the deadly galerina will be rusty as where the *Psilocybe cyanescens* will be purplish brown to black. Please be carefull and dont pick anything your unsure of, its just not worth dying over.

Ok... time to test yourself on some identification.
Below are some close ups of a *Psilocybe cyanescens* growing right next to the deadly galerina and some inky caps. There is only ONE *Psilocybe cyanescens* in these pictures.
The first 2 pictures will show top views, the 3rd pic will show the gills and stems of the mushrooms.
Then, the answer will be given in the following pics with a red arrow pointing out the *Psilocybe cyanescens*.
Can you tell the difference?

ANSWER

Well.. how did you do? This picture was staged. Sorry.. once again during all the excitement I should have tooken some better pictures. But none the less... in alder mulch, grass.. everywhere the galerinas were very close by.
A few last notes on the *Psilocybe cyanescens*.
One thing we found depressing is the psilocybe mushrooms are on a big decline in the Seattle area. Most landscaping is no longer being done with alder mulch, but there using some kind of red ceder mulch instead, and the psilo's dont thrive in that.
The places you want to look are anywhere that looks like fresh alder mulch has been planted in the last year or two. We found them right around ppl houses and buildings, in road dividers, in grass near alder mulch, around school campuses.. all sorts of places. The largest patches were about 8X the size of that little patch by the church, but I forgot my camera in the car...DOH!!!!

Plenty of spore prints were taken on wax paper. They are from the wild so they would probably require the use of agar to get them started. From there, I've had *Psilocybe cyanescens* grow on finche seed, you can use that as spawn to inoculate some alder wood chips and or sawdust. You can mix that in with some compost or straw even as shown in TMC, and case them with some good fertile soil. Planted in the spring or summer, given lots of water, in the fall when the rains come and the temps drop down to around 50-60f they should start fruiting for you. Its rare this mushroom can be grown indoors, but it has been done in a fridge from some pics I've seen of mj's. But your best bet is putting a patch outdoors.
As for the high.. well.. its very very potent, but tends to be a "speedy" high and gives me intense restlessness. I have a real hard time coming down and trying to sleep comfortably on this mushroom, and my muscles always ache from it. Its very visual when taken at least 3 dried grams, and at that dose.. hold on... because you'll be flying. I've talked with others that do not get this speeded out feeling from them,, and I've tripped with some friends that felt the same effects as me. Your milage may very. Many ppl really love this mushroom. It was certainly very beautiful to see in nature, and its a very tough, strong mushroom. The stems are very thick and hold up quite well while picking them. And from what I understand its pretty easy to grow outdoors if you live in the right environment.

A hugh thanks to John Allen for being our tour guide in Seattle WA, and showing us some beautiful pathces of *Psilocybe cyanescens*.

Growing tips for P. cyanescens

You dont need to make syringes from ps cyanescens, or inoculate grain as spawn. Prepare your alder wood, sterilize it. Preferable 4:1 alder sawdust to alder wood chips, small chips. Only use a small amount to start with, say about 6 to 8 cups worth of alder wood. Just scrape the spores directly on the the sterilized, moist wood. Incubate it, indoors at around 70f -75F. It will take a good 6-8 weeks for that wood to fully colonize.
Use that as more spawn to slowly start inoculating more larger volumes of wood for anther 2 months. Then plant your patch outdoors with more fresh alder wood. If you can get it planted outdoors by the end of April, you'll have good chances for it to fruit by fall. If not, they may not fruit until the following spring or fall.
Psilocybe cyanescens are slow growing. If you dont see germination, then lower the temps to about 55F for about 2 weeks. They are a temperate species so sometimes even to germinate they like the cold weather to begin with. After they start germinating and growing, you can bring the temps back up to around 70-75F to speed up the spawn run. But they still will only fruit outdoors when the climate is right, lots of rain and low temps between 45-60F.

Psilocybe cyanofibrillosa

Psilocybe cyanofibrillosa Guzmán & Stamets

---

synonyms:
Psilocybe rhododendronensis

DESCRIPTION 1

Description: Scattered to gregarious among bush lupines in alder and willow wood chips and bark mulch. Common among rhododendron gardens and nurseries and flood plains near river estuaries. From northern California (Eureka/Arcada) north to British Columbia, Canada. September to December. High in psilocin and low in psilocybin. Loses over 70% or more of their potency in drying.
A few hundred pounds of this species mixed with *Psilocybe cyanescens* was collected from mulch piled along side of I-5 highway on both sides of the road between Eureka and Arcada, California. I myself have only collected this species a few times in a twenty year period.

Psilocybe cyanofranciscana

synonyms:
Psilocybe allenii Borov., Rockefeller & P.G.Werner (2012)
Psilocybe cyanofranciscana nom. prov.
Psilocybe cyanofriscosa (improper latin): *Cyclone Psilocybe*

Macroscopic feat.:

Cap/Pileus: 20-40+ mm in diameter, convex to broadly convex to plane at maturity. Very light brown maturing to light yellow to grayish white upon drying. Surface viscid. Flesh white soon bruising bluish green.
Stem/Stipe: 30-70+ mm in length, yellowish. Flesh dramatically bruising bluish green where injured. Partial veil cortinate sometimes leaving an annular zone.
Gills/Lamellae: Attachment adnate to adnexed. Grayish coloration in young fruit bodies becoming purplish brown in maturity.

Microscopic feat.:

Basidio/Spores: 10.5 -12.5 (13.5) µm in length, ellipsoid, dark purplish brown in deposit. Slightly larger than *Psilocybe cyanescens* spores (9-12 µm.).

Habitat: Wood debris, landscaped areas.

Comment: *Psilocybe cyanofranciscana* is a newly acknowledged species in the California Bay Area and has not yet been officially described. The name "*Psilocybe cyanofranciscana*" is provisional and probably won't be retained upon publication in a scientific journal
Stamets (2005) coined the name "Cyclone" Psilocybe to describe the cyclonic (swirled) growth of the mycelium on agar, a feature often not present. This is possibly an introduced species that appears to be aggressively spreading and perhaps displacing its close relative, *Psilocybe cyanescens*, but there is also evidence that this species has been present in San Francisco since at least 1975 (Duffy and Vergeer, 1977). Microscopically *Psilocybe cyanofranciscana* and *Psilocybe cyanescens* are virtually indistinguishable but the mushrooms are easily separated in the field based on macroscopic features. *Psilocybe cyanofranciscana* is typically larger, more squat, paler in coloration, and lacks the wavy cap margin, especially when young, of *Psilocybe cyanescens*. Superficially, *Psilocybe cyanofranciscana* resembles the smaller *Psilocybe cyanofibrillosa*, but the microscopic features do not agree and it doesn't appear to be closely related.

Studied material: PANAMA, Prov. Chiriqui, Cerro Punta, near Nueva Suiza, July 3, 1975, Dumont PA-2074 (Holotype NY; Isotype at ENCB).

Discussion: This species is close to *Psilocybe yungensis* Sing. S. Smith, but differs in the smaller and brownish cheilocystidia. The brownish cheilocystidia connects *Psilocybe dumontii* with those species described by Guzmán (1977-A) from the tropical rain forests of Mexico such as *Psilocybe singerii* Guzmán, *Psilocybe weldenii* Guzmán and others. The species is named after Dr. K. Dumont, collector of the type material, in recognition of his enthusiastic mycological work in South America.

Macroscopic feat.:

Cap/Pileus: 1.5-3.8 cm broad. Convex, expanding to broadly convex to nearly plane, often with a central shallow umbo. Surface smooth to slightly translucent-striate near the margin, viscid when moist, reddish brown when young, becoming ochraceous, hygrophanous, fading in drying to dull straw colored. Flesh whitish, bruising bluish.
Gills/Lamellae: Attachment adnate, dull brown, soon becoming purplish brown, and eventually dark violaceous gray with whitish edges.
Stem/Stipe: 65-86 mm long by 2-2.5 mm thick. Covered with silky fibrils, equal to swollen at the base (4-5 mm thick) to which whitish rhizomorphs are attached. Partial veil cortinate, leaving a fugacious fibrillose annular zone in the upper regions.

Microscopic feat.:

Basidio/Spores: Spores purplish brown in deposit, subellipsoid, 9-13 by 5.5-6.6 µm.
Basidia: 4-spored.
Pleurocistidia: 17-30 by 5.5-7.7 µm, fusoid-ventricose to mucronate to sublageniform with short necks 2-3 µm thick.
Cheilocystidia: 15-25 by 4.4-6.6 µm, fusoid-ventricose to sublageniform, with elongated necks 4-5 µm long by 3-4 µm broad.

Habitat: Solitary to gregarious on soils rich in woody debris, often in grassy areas with *Eucalyptus* trees. Reported from New South Wales, eastern Australia.

Comment: Thought to be moderately active, but no analyses have yet been reported. Chang and Mills (1992) sought to show synonymy between *Psilocybe australiana*, *Psilocybe eucalypta*, *Psilocybe subaeruginosa* and *Psilocybe tasmaniana*, although, in the opinions of Guzmán, Bandal, and King (1993) and myself, they failed to conclusively prove their case. (See comments under *Psilocybe subaeruginosa*). Additionally, I find it difficult to accept their concept that, given the nature of close relatives in the genus *Psilocybe*, the same species can be both a coprophilic and lignicolous species. Hence, I am following Guzmán and treating these taxa as separate entities until further studies prove otherwise.

Discussion: *Psilocybe farinacea* is very close to *Psilocybe caerulescens* Murr., but differs in the size of the spores and cheilocystidia. This species was named by Rick and sent to Lloyd but, apparently, was never described. Its bluing indicates that this species probably is hallucinogenic.

Psilocybe fuliginosa

Psilocybe fuliginosa (Murrill) A.H. Sm.

synonyms:
Astylospora fuliginosa Murrill (1918)
Psathyra fuliginosa (Murrill) Murrill (1918)
Atylospora fuliginosa Murrill (1918)

Description: Following data comes from couple sources: Spores and comment are taken from *Psilocybe fuliginosa* species description in Mycologia 40 (6): 697. Pileus, stipe, lamellae, distribution and some of spores comes from *Astylospora fuliginosa* synonym description from Mycologia 10 (1): 25.

Macroscopic feat.:

Cap/Pileus: Hemispheric, not expanding, not umbonate, gregarious, 2 cm broad and 1 cm high; surface smooth, glabrous, hygrophanous, slightly striate, uniformly fuliginous, becoming somewhat paler on the disk; margin straight, eroded, concolorous.
Gills/Lamellae: Adnate, broad, ventricose, subcrowded, fuliginous, entire on the edges; spores usually ovoid, tapering at one end, smooth, purplish-brown, 7 x 4-5 µm.
Stem/Stipe: Equal or somewhat larger below, slender, smooth, glabrous, concolorous, whitish toward the base, 4-5 cm long, 1.5-2 mm thick.

Microscopic feat.:

Basidio/Spores: 6-7 x 4.5-5.5 µm, smooth, typically triangular in optical section but varying to ovoid or ellipsoid (as seen in face view), ellipsoid in side view, sordid yellowish brown when revived in KOH, with an obscure apical hyaline germ pore. Tapering at one end, purplish-brown, 7 x 4-5 µm

Distribution: Type collected in damp soil at Morce's Gap, near Cinchona, Jamaica, 1500 m elevation, December 29, 30, January 2, 1908-9, *W.A. & Edna L. Murrill 748* (herb. N. Y. Bot. Gard.). Also collected at the same time and place, *W.A. & Edna L. Murrill 680*.

Comment: Dr. Burke has sent me material from Alabama which appears to belong here though the spores vary slightly, being somewhat longer. They range from 6.5 to 8 µm. For *Psilocybe fuliginosa* the habitat on bare earth, the dry pileus, shape of spores in face view, and fuligineous cast of the carphophore are apparently distinctive. Murril described it as *Atylospora fuliginosa* (Mycologia 10: 25, 1918).

Discussion: This species is close to *Psilocybe brasiliensis* but the absence of pleurocystidia, the structures of the subhymenium, as well as the size of the spores and cheilocystidia separate it clearly from the latter. This species is named in honor of Dr. J.S. Furtado who helped the author collected this and other fungi in Brazil.

Psilocybe galindoi

Psilocybe galindoi Guzmán Nova Hedwigia

synonyms:
Psilocybe galindoi var. *Georgia ATL#7* Large Sclerotia
Psilocybe galindii

Macroscopic feat.:

Cap/Pileus: 10-30+ mm in diameter, broadly convex to plane at maturity. Surface dry.
Stem/Stipe: 100-150 mm in length. Flesh bruising bluish green where injured. Partial veil cortinate.
Gills/Lamellae: Attachment adnate to adnexed.

Microscopic feat.:

Basidio/Spores: 9.8-11.2 µm, subrhomboid to subellipsoid, dark purplish brown.

Habitat: Enriched Soils, Grasslands. Climate Warm temperate.

Comment: This species forms sclerotia invitro. See also *Psilocybe mexicana* and *Psilocybe tampanensis*.
Initially, this sample was described as *Psilocybe atlantis* and we assumed that was correct since no similar species were known in Georgia. Samples sent to Psilocybe expert Gaston Guzmán cast some doubt on the mushroom's actual identity, but no alternative identification was suggested.
A direct comparison of samples with the published description of *Psilocybe atlantis* has confirmed Guzmán's findings. The strain ATL#7 is not *Psilocybe atlantis*, but is instead a related species in the Section Mexicanae. This new collection closely resembles *Psilocybe galindoi* (galindii), a species previously known only from Mexico. For lack of a better name, we are going to unofficially call this sample *Psilocybe galindoi* var. *Georgia*. If this species is described in a scientific journal and given a different name, we will amend this description. Efforts are now underway to provide authenticated spore samples of *Psilocybe atlantis*.
Both species can be viewed in the Sporeworks Microscopy Gallery Section Mexicanae for side by side comparisons of microscopic features. Note that the authentic *Psilocybe atlantis* cheilocystidia are irregularly branched and the *Psilocybe galindoi* var. *Georgia* are unbranched. *Psilocybe atlantis* spores are also somewhat smaller. Currently, no mushrooms matching this collection have been described as occurring in the United States.

Psilocybe germanica

Psilocybe germanica Gartz (2015)

Discussion: *Psilocybe germanica* was described as a new taxon from Germany. This species was found to be autumnal and lignicolous, living in soils enriched with deciduous wood-debris, and featured strong blueing behaviour after bruising and ageing. It contained high amounts of psilocybin and baeocystin. This mushroom appears to be the first described species derived from wood chips that contains significant amounts of baeocystin in the absence of psilocin. The novel species was differentiated from other psychoactive taxons such as *Psilocybe cyanescens*, *Psilocybe azurescens* and *Psilocybe bohemica* in combination from features of the stipes and caps. As it was observed previously with the potent psychoactive species *Psilocybe cyanescens*, it is expected that *Psilocybe germanica* might be found to achieve a remarkably wide area of distribution in the future given the modern use of mulch in parks and gardens.

Macroscopic feat.:

Cap/Pileus: 1-4 cm in diameter, always broadly umbonate, rarely flattening to a little turn up in age with a persistent broad umbo; no traces of a veil at any stages, hygrophanous, moist deep brown, lacking a separable pellicle, margin not wavy, not striate, not translucent when moist, fading in drying to whitish; during development soon a spontaneous gray-bluish colouration on the umbo occurs, at age an additional strong blueing develops, particularly after rains and during freezing; bruising of the white flesh also yields a strong blue colour, odour pleasantly aromatic.
Stem/Stipe: 5-9 x 0.3-0.7 cm, characteristic enlarged at the pileus, sometimes the thickening often impressed as a joint, in which the upper end of the handle with the cap then drops; dry, white, not very hard, not flexuous, always curved, often multiple times, without traces of a veil, no fine mycelia on it, sometimes solid lumps visible as a rub, easily staining deep blue when touched at all parts; at first touch sometimes green discoloring until a very fast-moving to deep blue; the wood-like layer in the thickening shows no blueing at all, stuffed with white mycelia at first, later hollow, rhizomorphs on the base, keeping wood substrate together.
Gills/Lamellae: At first brownish then dark purple-brown, closely set, alternating adnexed to adnate.

Microscopic feat.:

Basidio/Spores: 9-12 x 5.5-7.5 µm, with a clear germ pore.
Cheilocystidia: Lageniform, numerous, 25-33 / 6.0-8.3 µm.
Pleurocistidia: Absent.

Habitat: Gregarious to cespitose on deciduous on wood chips from various plants, also on bark in mixture with soil and other wood debris.

Distribution: Until now, the mushrooms have only been observed to grow in parks. Holotypus: a gathering (8th October 2014, Dippoldiswalde, Germany) is deposited in the herbarium of the botanical museum Berlin / Dahlem (B).

Season: Observed growing is from September to December.

Comment: The tiny species *Psilocybe serbica* Moser & Horak showed features for caps and stipes similar to *Psilocybe bohemica*. The microscopic features are comparable to other wood-loving Psilocybe species as is the case with *Psilocybe germanica*. Chemical analyses of five *Psilocybe germanica* mushrooms samples revealed the presence of significant amounts of psilocybin and baeocystin. This was consistent with qualitative TLC analysis of 30 samples from 2013 and 35 extracted samples from 2014 and psilocin was not detected.
Psilocybe germanica showed similar alkaloid levels to what is known about *Psilocybe semilanceata* with only traces of psilocin. *Psilocybe azurescens* is generally considered more potent and, in addition to psilocybin and baeocystin, is also displaying comparatively large amounts of psilocin. Both *Psilocybe cyanescens* and *Psilocybe bohemica* typically show the presence of psilocybin and traces of baeocystin. A large variation in psilocybin levels are frequently encountered. In contrast to *Psilocybe bohemica*, *Psilocybe cyanescens* can also contain large amounts of psilocin. In addition, the new indole derivative aeruginascin was not detected in any of the mushrooms. As far as it is currently known, this trimethylammonium analog of psilocybin has only been reported to occur in the hallucinogenic species *Inocybe aeruginascens* Babos. *Psilocybe semilanceata* is the best studied psychoactive mushroom species in the world and is known to contain psilocybin and baeocystin. Previous investigations in 1994 have shown that the use pure methanol yielded the authentic indole derivatives from dried mushrooms and the use of aqueous solvents resulted in hydrolysis of psilocybin and baeocystin to give psilocin.

Discussion: *Psilocybe gallaeciae* belongs to section *Mexicanae* Guzmán, following GUZMÁN (1983) for the form and size of their thick-walled spores, and its bluing basidioma. For the pseudorhiza it is closely related to *Psilocybe galindii* Guzmán (1983) from Mexico and *Psilocybe antioquensis* Guzmán et al. (1994) from Colombia, but those species have cheilocystidia 14-19 µm long and 15-20 µm long, respectively. *Psilocybe mexicana* R. Heim has neither pseudorhiza nor pleurocystidia, and it is known only from Mexico and Guatemala. This is the first record of a species of the section *Mexicanae* found in Europe. Their members are known from Mexico, U.S.A. (Florida), Colombia, Brazil and Thailand (Guzmán, 1995). The local Galician people use *Psilocybe gallaeciae* recreationally for its hallucinogenic properties. *Psilocybe serbica* reported by Freire et al. (1994) from Galicia, without any description, probably is *Psilocybe gallaeciae*. *Psilocybe serbica* belongs to section *Semilanceatae* and it is known only from central Europa (Guzmán, 1983).

First reported in the literature in 1997, Gastón Guzmán placed *Psilocybe guilartensis* in Psilocybe section Brunneocystidiatae due to its blue staining reaction, small thick-walled subrhomboid spores, and pigmented cystidia. Other mushrooms in the section Brunneocystidiatae include *Psilocybe banderillensis*, *Psilocybe banderillensis* var. *paulensis*, *Psilocybe brunneocystidia*, *Psilocybe heimii*, *Psilocybe inconspicua*, *Psilocybe pleurocystidiosa*, *Psilocybe rzedowski*, *Psilocybe singerii*, *Psilocybe uxpanapensis*, *Psilocybe veraecrucis* and *Psilocybe weldenii*.

Discussion: The discovery that all collections of *Psilocybe guilartensis* s have setaceous hyphae at the base of the stipe is a significant addition to the circumscription of this taxon and provides a very helpful character in distinguishing this species. The distinctive pleuro- and cheilocystidia also are important characters that help to define *Psilocybe guilartensis*. *Psilocybe guilartensis* is the most common species of *Psilocybe* collected in Puerto Rico, as evidenced by the numerous collections documenting its abundance. It tends to fruit on bare clay along hiking trails where disturbance has occurred. Its relative abundance might be the result of being collected in readily accessible areas.
The record from the Dominican Republic is the first report of this species from the island of Hispaniola, although this collection (*Baroni 9028*) lacks the yellowish or grayish opaque pleurocystidia and the brownish or grayish opaque cheilocystidia that are typical of *Psilocybe guilartensis*. However, the presence of the highly distinctive setaceous hyphae at the base of the stipe indicates this collection has strong phenotypic affinities with *Psilocybe guilartensis*. The lack of pigments in the hymenial cystidia might be due to the immaturity of the specimens that make up this collection. For now, based on macromorphology, basidiospore morphology and setaceous hyphae at the base of the stipe, we consider this collection as conspecific with *Psilocybe guilartensis*.
As pointed out by Guzmána et al (1997) *Psilocybe guilartensis* belongs in section *Brunneocystidiatae* because of the pigmented hymenial cystidia, thick-walled rhomboid or subrhomboid basidiospores that are less than 8 µm long and bluing of the basidiomata when injured. The setaceous hyphae at the base of the stipe, the two distinct types of pleuro- and cheilocystidia, especially the hyaline inflated cheilocystidia with encrusted bases and bifurcate branched apices, are features that clearly separate *Psilocybe guilartensis* from the similar *Psilocybe pleurocystidiosa* (Guzmán 1983).

Psilocybe herrerae

Psilocybe herrerae Guzmán (1978)

Macroscopic feat.:

Cap/Pileus: 0.8-1 (1.9) cm broad. Conic to convex, sometimes papillate. Surface smooth to dry, finely fibrillose-rimose. Brown to sepia brown, hygrophanous, fading in drying to yellowish, sometimes with bluish tones. Flesh white, bruising bluish where injured.

Microscopic feat.:

Basidio/Spores: Dark purplish brown in deposit, subellipsoid in side view and subrhomboid in face view, 5-6 by 3.3-4.9 µm.
Basidia: 4-spored.
Pleurocistidia: 12-25 by 6-8.8 µm, primarily fusoid-ventricose, few are ventricose-rostrate with an abbreviated neck.
Cheilocystidia: 13-23 (27) by 5.5-7.7 µm variable in form, 7-11 by 1.5-2.5 µm, sometimes irregularly forking.

Habitat: Solitary to gregarious, often along road cuts, in soils high in sand and clay, and in open forests dominated by pines, sweetgums, and oaks. Found in June and July in Chiapas and Veracruz, Mexico.

Comment: Judging by the rapid bluing reaction, *Psilocybe herrerae* is probably potent, but it has not yet been analyzed. The long pseudorhiza delineates this species from most others. Psilocybe hispanica

Psilocybe hispanica Guzmán (2000)

The *Psilocybe hispanica* is a new species discoverd by Ignacio Seral in 98' growing high in the hills of spain. It tends to grow in colder temps, and has even been seen growing in snow. This mushroom was fround growing on horse dung, next to patches of *Psilocybe semilanceata*'s. The discoverer of the *Psilocybe hispanica* contacted Paul Stamets last October, unfortuanatly Stamets schedule was to full and a European mycologist named Giorgio Samorini from Italy flew to spain and did some research to find this was a whole new mushroom and classified it as the *Psilocybe hispanica*. Rumor also has it this mushroom will be featured in Paul Stamets next book Psilocybe Mushrooms of the World, Part 2 (cant wait for that one, I'm sure it will be another excellent book by Paul). We do have spore prints of this species currently, and may have some syringes soon. Its potency is said to be a very nice clean high, more potent then cubensis, but less potent then azures, more closely to that of *Panaeolus* species.
Some more detailed information from Ignacio on this mushrooms growing conditions.
The hispanica appears in horse dung about the 1 of october and finish about the 1 of november.... at 1700- 2000 metres high.... the latitude of spain makes the altitude date more relevant... keep in mind that in those mountains water become ice at night and the hispanicas resist freezing temps very well so there is a very cold temps at night about +5 to -5 at night and +5 to 20 at the daytime always celsius degrees.
New information from a *Psilocybe hispanica* fruiting in San Francisco, CA, USA Feb, 2000 !!!!
Yes.. the *Psilocybe hispanica* has been fruited now !!! A big atta boy goes out to Raja from San Francisco for fruiting the *Psilocybe hispanica*. What amazed me is it only took 3 months from inoculation to fruiting. Most of us were assuming a year long outdoor bed, so this is great news for us to get motivated on this new species.

Gills/Lamellae: Attachment adnate to adnexed, pale brown to coffee colored, and eventually purplish black at maturity.
Stem/Stipe: (30) 50-90 (110) mm long by 1-3 mm thick. Equal to slightly thickened near the base, flexuous, sometimes twisted. Whitish to brownish red near the base, easily bruising bluish to bluish black. Partial veil thinly cortinate, fragile, soon disappearing.

Microscopic feat.:

Basidio/Spores: Dark purplish brown in deposit, rhomboid to subrhomboid, (5) 6.5-8 (9.6) by 4-5.6 µm.
Basidia: 4-spored, rarely 2-spored.
Pleurocistidia: 16-36 by 8-12 µm, ventricose to clavate, often irregular.
Cheilocystidia: (15) 19-35 by 4.4-6.6 µm, lageniform, narrowing into a long neck 1-3 µm, either acute or subcapitate at the apex.

Habitat: Solitary to gregarious in muddy clay soils in subtropical coffee plantations. Found in June and July in Mexico (Puebla, Oaxaca, and Chiapas) and in February in Argentina. Also reported from Brazil and Colombia.

Comment: Moderately active. Specimens from Brazil yielded up to 0.30% psilocybin and 0.30% psilocin (Stijve and de Meijer 1993). A variety of this mushroom, *Psilocybe hoogshagenii* Heim var. *convexa* Guzmán is only slightly umbonate, has a convex cap, and is conspecific with *Psilocybe semperviva* Heim i Callieux. This variety is most common in the state of Puebla, Mexico, and to a lesser degree in the states of Oaxaca and Hidalgo, fruiting from June to August. One of the most unusual looking Psilocybes yet discovered, this mushroom is quite potent. Heim and Hofmann (1958) found 0.60% psilocybin and 0.10% psilocin (as *Psilocybe semperviva* Heim and Caillieux) from cultivated specimens. Guzmán (1983) reported that this mushroom grows at 1000-1800 meters in elevation (Argentina) and is commonly seen by coffee growers who report massive flushes coming up in unison and soon disappearing. See also *Psilocybe brasiliensis*.

Hypodermium: Subcutis of cylindrical, hyaline, pigmentless hyphae. Clamp connections present.

Habitat: Gregarious in small groups on soil among litter in *Araucaria cunninghamii*. Known from Papua New Guinea only.

Studied material: PAPUA NEW GUINEA, Morobe District, Bulolo, Susu; 15. I. 1973, leg. HORAK (Holotype ZT, 72/751; isotype in ENCB).

Discussion: This small *Psilocybe* is a very distinct species. *Psilocybe inconspicua* has no obvious relationships to other taxa of this genus except with some species described by Guzmán (1977) from the tropical forests of Mexico. The brownish cheilocystidia represent the most prominent taxonomic character. Due to its systematic position it is likely that *Psilocybe inconspicua* is an hallucinogenic fungus.

Macroscopic feat.:

Cap/Pileus: (0.5) 1-2 cm broad. Hemispheric to convex, expanding to broadly convex to nearly plane to slightly umbonate. Reddish brown to brick brown to tan or yellowish brown, hygrophanous, fading in color to straw. Margin translucent-striate most way to the disc when moist from a separable gelatinous pellicle, becoming opaque in drying, and sometimes decorated with whitish floccose scales.
Gills/Lamellae: Attachment adnate to subdecurrent, reddish brown to purplish gray-brown, with concolorous edges.
Stem/Stipe: 20-40 mm long by 1.5-2 mm thick. Equal, flexuous, hollow, whitish to reddish brown, adorned with whitish to brown firbils toward the base, which often has whitish mycelium attached. Partial veil cortinate, soon desappearing.

Microscopic feat.:

Basidio/Spores: Purplish brown in deposit, 7-8.8 (10) by 4.5-6.6 µm, subrhomboid to subellipsoid in face view, subellipsoid in side view
Basidia: 4-spored.
Pleurocistidia: Absent.
Cheilocystidia: Lageniform to sublageniform, (15) 18-38 na 5-8 µm, with a long neck 2.5-3.8 µm broad.

Habitat: Solitary to gregarious, commonly on the base of grass stems in open areas, occasionally on rotting twigs or in rich soils. A temperate species, *Psilocybe inquilina* is widely distributed, reported from North America (California, Oregon, and Washington), South America (Argentina, Chile, and Uruguay), and Europe (Denmark, Finland, France, Hungary, Sweden, and Switzerland). Undoubtedly more widely distributed than presently reported.

Comment: Not known to be active. I frequently find *Psilocybe inquilina* growing from the bases of matted, rotting grass in the fall. The mushrooms are difficult to harvest without either the stems breaking or clumps of dead grass being pulled up with each specimen. This feature, combined with the nearly decurrent gills, the convex cap, and the deeply translucent-striate margins, distinguishes this species macroscopically. Psilocybe kumaenorum

Psilocybe kumaenorum R.Heim (1967)

Discussion: *Psilocybe kumaenorum* is known as *koull tourroum*, *kougltourroum* or *koobl tourroum* in Yuwi [Heim 1967] (Yoowi [REAY 1959]), the language of the Kuma (Heim 1967: 186; Heim 1978). However, Heim (1967: 186) suggested that the Kuma used these names for a variety of different mushrooms, so they are possibly of little use in distinguishing P. kumanorum from other mushroom species found at Kondambi.

Macroscopic feat.:

Cap/Pileus: 5-7 mm in diameter, peak mamillate and punctate, but not papillate, flattened and very irregular, with an edge largely lobed/notched, often fairly roughly, rolling up tightly at the beginning; at first campanulate and entirely black-brown, then darkish crimson/purple around the circumference (K. 65) with a centre of flesh-coloured cream (128C/153C) or orange colour; sometimes with subtle greenish tones; orange-yellow, cream or light ochre (K. 157'162) or greenish (+ K.245) at the peak of the mamilla; at the edges marked with not very thick but clear stripes of a very dark violet (K.544 dark); very hygrophanous, blanching quickly (cream), as demonstrated by the desiccation of little whitish spots. Flesh brownish, with the scent of flour (Heim 1967: 186).
Gills/Lamellae: Firstly cream, then ochre, then mauve/mallow or pale orange-mauve (K.109 light), finally violet with purple tint (+ K.105), at the edges white and remaining so; adnexed. *Psilocybe kumaenorum* lacks pleurocystidia (Guzmán 1983; Guzmán et al. 1991: 508).
Stem/Stipe: Reaching 2.7 cm , 1.3 mm width, 2.5 mm at the base which is lightly but clearly bulging; at first white and marked with fine, very straight longitudinal furrows, of greyish brown, silvery at the top where there are fine remnants of a delicate, silky, white cortina; at the bottom: hollow, with a violet-red cortex, light green on the exterior (K.303 C) or grey tending slightly towards blue (K.325); flesh orange yellow (K.137).

Habitat: Grassy, humid places around the village of Kondambi, circa late August, 1963 (Heim 1967: 186). *Psilocybe kumaenorum* grows on soil in small groups and in open places among grass (Allen et al. 1991: 65).

Gills/Lamellae: Adnexed, close to distant, dark chocolate brown to purplish brown.
Stem/Stipe: 14-30 mm long x 1-2 mm thick. Equal to swelled at base. Whitish to pale brownish and staining blue when injured.

Psilocybe luteonitens

Psilocybe luteonitens (Fr.) Park.-Rhodes 1951

synonyms:
Stropharia umbonatescens (Peck) Saccardo
Stropharia luteonitens, [RSD]

Macroscopic feat.:

Cap/Pileus: 1-4 cm broad. Conic-campanulate with a distinct umbo, expanding to convex to broadly convex to nearly plane with or without an acute-to-low umbo. Margin decorated with fragile whitish remnants of the partial veil. Yellowish to pale ochraceous brown toward the disc. Surface viscid when moist from a separable gelatinous pellicle. Flesh thin, pallid.
Gills/Lamellae: Attachment adnate to subdecurrent, close, broad. Color whitish at first, then grayish, and eventually purplish brown.
Stem/Stipe: 35-70 mm long by 2-4 mm thick. Equal and slender. Pallid to yellowish, lighter than the cap. Surface powdered above the annular region, and initially covered with fine fibrils below, but often smooth with age. Partial veil thinly membranous, floccose, leaving an obscure evanescent annular zone of fibrils, if at all.

Microscopic feat.:

Basidio/Spores: Dark purplish brown in deposit, subellipsoid to ellipsoid, 15-19 (22) by 10-11 µm.
Basidia: 2-spored.
Pleurocistidia: Absent.
Cheilocystidia: 25-45 by 3-7 µm, cylindrical to sublageniform with a flexuous, elongated apex.

Habitat: Gregarious on dung in the fall in the Pacific Northwest. Reported from Washington, Oregon, Idaho, Michigan, and New York in the summer to early fall. Also reported from Mexico, Europe, and Asia.

Comment: The habitat preference, distinctly umbonate and yellowish cap, and the white membranous partial veil all make this species easy to recognize. Additionally, the veil remnants usually adhere to the cap margin rather than the stem, especially evident when young. See also *Psilocybe semiglobata* and *Psilocybe fimetaria*.

Macroscopic feat.:

Cap/Pileus: 1,5-6 cm broad. Obtusely umbonate to campanulate to convex, expanding to broadly convex to plane and often umbonate, with an elevated margin in age. Surface viscid when moist from a thin gelatinous pellicle, smooth, covered with scattered, white, floccose scales, increasing towards margin. Pale grayish yellow to ochraceous to brownish orange, and darker towards the disc, not strongly hygrophanous.
Gills/Lamellae: Attachment adnate to sinuate, broad, close, pallid, white at first, soon grayish brown and finally dark purplish brown with whitish fringed margins.
Stem/Stipe: 50-85 mm long by 4-7 mm thick. Hollow, equal to enlarged towards the apex and tapering below. White to dingy yellowish. Partial veil membranous, leaving a thick, white membranous annulus, often flaring, which can deteriorate into an annular zone, below which the surface can be covered with fibrillose patches. Flesh moderately thick, firm, whitish, and not bruising.

Microscopic feat.:

Basidio/Spores: Dark purplish brown in deposit, smooth, ellipsoid 13-15 by 6-8 µm.
Basidia: 4-spored.
Pleurocistidia: Absent.
Cheilocystidia: 33-44 by 4-5 µm, nearly clavate to sublageniform, with an elongated neck 3-4 µm thick.

Habitat: Scattered to gregarious, preferring sandy soils, alluvial plains, and/or soils rich in woody debris of *Salix* (willow) and *Almus* (alder). Found from May to November in the United States (Alaska, Washington, Oregon, possibly Colorado), northern Europe, and the British Isles. Likely to be much more widely distributed than presently reported.

Comment: Not active, edibility unknown. The well-developed membranous annulus, the nonbluing flesh, its modest size, and its habitat, all give clues to its identification. This mushroom is similar to *Psilocybe squamosa* and *Psilocybe thrausta*, and can be separated with certainty by the length of the cheilocystidia. *Stropharia riparia* is generally similar. synonyms:

Hypholoma cyanescens Maire

Macroscopic feat.:

Cap/Pileus: 1,5-3,5 cm broad. Convex to campanulate to conic-campanulate, expanding with age, but not umbonate. Surface viscid when moist from a separable gelatinous pellicle. Orangish brown, becoming olive toned, hygrophanous, fading in drying to yellowish white. Flesh amber, bruising bluish where injured.
Gills/Lamellae: Attachment adnate, pallid at first, soon darkening, becoming purplish brown with the edges remaining whitish fringed.
Stem/Stipe: 25-75 mm long by 2-5 mm thick. Equal to slightly enlarged towards the base. Whitish to yellowish white, bruising bluish where injured. Surface pruinose above and finely fibrillose below.

Microscopic feat.:

Basidio/Spores: Dark purplish brown in deposit, elongate-ellipsoid, 10-12 (13.5) by 5.5-7 µm.
Basidia: 4-spored.
Pleurocistidia: Absent or near to gill edge.
Cheilocystidia: 30-40 by 6-8 µm. Variable in form: lageniform, fusiform, or ampullaceous.

Habitat: Known only from North Africa (Morocco and Algeria) in October through December. Grows gregariously on soil rich in woody debris, in forests mixed with pine (*Pinus pinaster*), fir (*Abies pinsapo*) and oak (*Quercus ilicis* and *Quercus pyrenaica*). The identification of collections from Europe as *Psilocybe mairei* are doubtful, and according to Guzmán' (1983) were probably *Psilocybe serbica* and allies.

Comment: Probably potent, judging by the bluing reaction, although no analyses have been published. This is the only wood-decomposing, bluing *Psilocybe* reported from North Africa. Prior to the expansion of the Sahara desert, North Africa enjoyed a moister climate and undoubtedly hosted many more mushrooms than are known today. One wonders if *Psilocybe mairei* is a surviving remnant of a species that was once much more common. I am reminded of the cave art representing a beelike shaman undergoing a mushroom experience from the Tassili plateau in Northern Algeria, and I'm struck by the fact that this is the only species of *Psilocybe* presently known in that area. Given that the Tassili plateau was running with rivers at the time the artist lived, the alluvial plains would have been perfect for supporting species like *Psilocybe mairei*. Could this have been the mushroom the artist used? See also *Psilocybe cyanescens*, *Psilocybe serbica*, and allies.

Psilocybe makarorae

Psilocybe makarorae P.R.Johnst. & P.K.Buchanan (1995)

Macroscopic feat.:

Cap/Pileus: 1.5-3.5 cm in diameter. Conic to campanulate, expanding in age to broadly convex, usually with a pronounced umbo. Surface tacky to dry. Yellowish brown to orangish brown, fading in drying, and lighter towards the margin, which is striate when moist. Flesh whitish, bruising greenish blue where injured.
Gills/Lamellae: Attachment adnexed, pale grayish brown with concolorous edges.
Stem/Stipe: 30-60 mm long by 2-4 mm thick, equal, white to brownish near the base, which radiates white rhizomorphs. Partial veil cortinate, leaving fibrillose veil remnants along the cap margin when young, soon disappearing, but not forming an annular ring on the stem. Surface finely fibrillose and silky.

Microscopic feat.:

Basidio/Spores: Dark purplish brown in deposit, ellipsoid in side view, ovoid to subrhomboid in face view, (6.5) 7.5-10 by 4.5-6.5 µm.
Basidia: 4-spored.
Pleurocistidia: Similar to cheilocystidia ventricose-rostrate to mucronate, 4-8 µm thick, with a simple neck, 2.5-4 µm long.
Cheilocystidia: 18-26 by 6-9 µm, ventricose-rostrate to mucronate with a short, simple neck 3-5 µm long.

Habitat: Found scattered to gregarious on rotting wood and twigs (*Nothofagus*) near lakes and picnic grounds in the vicinity of Makarora, New Zealand (Otago Lakes and Franz Josef Glacier) in the fall. Probably more widely distributed.

Comment: Potency unknown but probably moderately active given the bluing reaction. This newly described species by Johnston and Buchanan (1996) resembles *Psilocybe caerulipes*, but the presence of pleurocystidia and longer-necked cheilocystidia delineates *Psilocybe makarorae* from this taxon. Worthy of note is that the two authors work closely with, are consulted by, and paid by law-enforcement officials to help in the prosecution of unlucky collectors. See also *Psilocybe australiana*, *Psilocybe eucalypta*, *Psilocybe subaeruginosa*.

Psilocybe mammillata

Psilocybe mammillata (Murrill) A. H. Sm. 1948

Macroscopic feat.:

Cap/Pileus: (0.5) 1-3 (1.5) broad. Conic, expanding to campanulate at maturity, and often umbonate. When moist, surface smooth, slightly striate near the margin, which is often adorned with minute remnants of the partial veil. Reddish brown to brownish olivaceous, hygrophanous, fading to beige or dirty yellowish orange from the disc, occasionally with blackish tones. Flesh pale brown, bruising bluish.
Gills/Lamellae: Attachment adnexed, pale brown to dark purplish brown, thin, with whitish edges.
Stem/Stipe: 15-30 mm long by 1-2 mm thick. Equal to slightly swelling at the base from which white mycelium radiates. Yellowish at first, soon reddish brown with maturity, often retaining whitish patches near the base. Flesh reddish brown, bruising bluish where injured. Partial veil cortinate, fragile, soon disappearing in age.

Microscopic feat.:

Basidio/Spores: Dark purplish brown in deposit, subellipsoid in side view, rhomboid to subrhomboid in face view, 5-6.5 (8) by 3.5-5.5 µm.
Basidia: 4-spored.
Pleurocistidia: Absent or only near to the gill edge.
Cheilocystidia: 12-17 by 4.5-5 µm, fusoid-ventricose with elongated necks, 3.3-5 by 1-2.5 µm.

Habitat: Solitary to gregarious, infrequently cespitose, in soils rich in woody debris, in humus, and sometimes on clay soils. Found along trails, shady banks, and in coffee plantations. Discovered by Dr. Thiers in Florida Highlands Hammock State Park). Also reported from Jamaica, Mexico, and Bolivia.

Comment: Guzmán et al. (1993) reports that this species is active, although no analyses are cited. The classic bluing reaction leaves little doubt about its activity, although estimation of potency would be purely speculative. This mushroom is probably widely distributed throughout much of Florida but goes unrecognized by most hunters of the more massive *Psilocybe cubensis*.

nonactive

Macroscopic feat.:

Cap/Pileus: 1-4 cm broad. Campanulate-hemispheric to convex to broadly convex, and sometimes slightly umbonate, finally expanding to place with age. Margin translucent-striate when moist, and often appendiculate with remnants of the thin partial veil. Cinnamon brown to livid brown when moist, fading to ochraceous or yellowish brown, and remaining darker at the disc. Surface smooth and only moist to subviscid when wet.
Gills/Lamellae: Attachment adnate to subdecurrent, close to broad. Yellowish at first, darkening with spore maturity to a dark brown.
Stem/Stipe: 20-40 mm long by 1-3 mm thick. Pale yellowish to pallid. Surface covered by fine, dry fibrils. Flesh stuffed with a fibrous pith, tough, but soon becoming hollow. Partial veil thinly membranous, fugacious, soon deteriorating to an annular zone of fibrils in the median to lower regions of the stem, usually darkened by spores.

Microscopic feat.:

Basidio/Spores: Dark purple-brown in deposit, subellipsoid, 10-14 by 7-9 µm.
Basidia: 4-spored.
Pleurocistidia: Absent.
Cheilocystidia: 20-33 by 6.6-8.8 µm, fusoid-ventricose to sublageniform with a short neck 3.3-4.4 µm thick.

Habitat: Scattered to numerous on dung. Reported from California, Oregon, Washington, and the northern Midwest of the United States. Widely spread throughout the world, this mushroom has been collected in Canada, Europe, the former USSR, and Japan. *Psilocybe merdaria* is probably more widespread than the literature presently indicates. It prefers a temperate zone..

Comment: Not known to be active; not sufficiently studied for chemical content. In temperate zones, *Psilocybe merdaria* is common dung dweller, along with *Psilocybe semiglobata* and *Psilocybe papilionaceus*. The annulus is typically located in the lower regions of the stem, or at most mid distance, but not superior. This species is virtually identical to *Psilocybe moelleri*, which has larger spores: 13-14 (16) by 7-8 µm. See also *Psilocybe coprophila* and *Psilocybe subviscida*.

Psilocybe meridensis

Psilocybe meridensis Guzmán

Macroscopic feat.:

Cap/Pileus: (10-) 15-30 mm diam, conical to convex or subcampanulate, subpapillate or subumbonate, lubricous, even, slightly striate at the margin, yellowish brown or reddish brown, becoming paler towards the margin, readily turning blue-green to blackish when bruised or old.
Gills/Lamellae: Adnate or sinuate, yellowish gray to brownish violet or dark brown sepia, edges whitish and subfloccoses; turning blue-green to blackish when bruised.
Stem/Stipe: 40-80 x 3-5 mm, equally cylindrical or slightly thickened at the base, somewhat flexuous, hollow, whitish to irregularly reddish brown or blackish, readily turning blue-green when injured, covered by whitish floccose little scales, mainly toward the base. Veil well developed, cortinate and white, forming a complex subfibrillose or submembranous annulus, frequently double.
Context: Context pallid yellow in the pileus and stipe, whitish toward the pileus surface, readily turning blue-green to blackish when cut. Dried basidiomata are completly blackish to black.
Odor: Something special but fungus-like, not farinaceous. Taste slightly fungal, subfarinaceous to pungent.

Microscopic feat.:

Basidio/Spores: (5.5-) 6-7 (-8) x 3-4 x 3-3.5 (-4) µm, subellipsoid or subovoid both in face and side view, brownish yellow, thin-walled, with a broad germ pore at one end and an acute short appendage at the other.
Basidia: (16-) 17.5-24 x (4-) 5-6 µm, 4-spored, clavate ventricose, hyaline.
Pleurocistidia: (16-) 17.5-27 (-28) x (4-) 5-7 (-9) µm, common, hyaline, subfusoid with acute apex or sublageniform with a short neck.
Cheilocystidia: (14,5-) 16-28 (-31) x (4-) 5-6,5 µm, abundant, hyaline, ventricose sublageniform, frequently with a middle constriction with a short or long neck, sometimes bifurcate.
Subhymenium: Not well differentiated.
Trama: of gill regular, formed by hyaline to pale yellow hyphae, thin-walled 2.5-13 µm wide.
Epicutis: Subgelatinized, formed by 2.5-4 µm hyaline to pale yellow parallel hyphae.
Hypodermium: With hyaline or pale yellow hyphae or subglobose elements 5-17 µm, wide, thin to thick-walled. Clamp connections present.

Habitat: Gregarious on soil, in a subtropical forest ("bosque ombrofilo montano siempre verde") with *Cyathea* and *Blechnum* at 2400 m of elevation. Known only from the type locality.

Studied material: VENEZUELA:: Márida State, Parque Sierra Nevada, Telefárico de Márida, La Montana Station, May 23, 1993, Marcano & Guzmán s.n. (Guzmán 30806), (Holotype Herb. Univ. de Los Andes, Fac. Farmacia 8001; izotyp XAL).

Discussion: The presence of an annulus relates this species to *Psilocybe argentipes* Yokoyama from Japan and *Psilocybe graveolens* Peck from U.S., but the former has no pleurocystidia and the latter has broader spores [4.5-5(-6) µm] and hyaline to brownish pleurocystidia. Its habit is similar to that of *Psilocybe zapotecorum* and *Psilocybe angustipleurocystidiata*, but those species have no annulus, and the pleurocystidia are vesiculose submucronate or subfusiform, 5.5-14 µm wide in the former, and 3-6.5 µm wide in the latter. The strong blue-green to blackish or black reaction in all parts of the basidiome, including the gills, as well as the pungent taste, are two conspicuous features of *Psilocybe meridensis*.

Context: Whitish to pale grayish (4A2-3), with slight farinaceous odor and taste.
Odor: And taste slightly farinaceous.

Microscopic feat.:

Basidio/Spores: (9-) 10-11 (-13) x 6-7 (-8) x 6-7 µm, subrhomboid or subovoid in face-view, subovoid in side-view, thick-walled, wall up to 1 µm thick, yellowish-brown, with a distinct and broad germ pore at distal pole and a short asymmetric appendage in the other. Spore print dark chocolate (7E-4).
Basidia: 35-39 x 7,5-9 µm, 4-spored, subclaviform, hyaline.

Studied material: UNITED STATES, New Mexico: Mescalero Range, Sierra Blanca, Lincoln Co., near town Mescalero, July 2004, *Walstad* s.n. (holotype XAL, isotype NY).

Discussion: This new species belongs to section *Stuntzii* Guzmán (Guzmán 1983), because of the subrhomboid, thick-walled basidiospores, presence of an annulus, and the bluing feature. It differs from *Psilocybe stuntzii* Guzmán & J. Ott (Guzmán 1983, Guzmán & Ott 1976) for its more robust basidiomata with subradicating and strigose stipe bases and cheilocystidia lacking elongate and flexuous necks. *Psilocybe stuntzii* has a (5-) 10-20 (-35) mm diam pileus and lageniform cheilocistidia with long necks (Guzmán & Ott 1976). Also *Psilocybe stuntzii* is known only from the Pacific regions of Canada and the USA. Although information gathered by Walstad and friends is somewhat confusing, it is probable that *Psilocybe mescaleroensis* had or still has a sacred use among Indians.

Psilocybe mexicana „A“

Psilocybe mexicana „A“ Heim 1957

Psilocybe mexicana grows solitary to gregarious in meadows, often in horse pastures and in soils rich in manure. It is most common at 1000-1800 m in elevation. This species is found in June through September in subtropical Mexico.
This species was highly sought after for years because of it's sclerotia forming abilities. The two mexicana strains we sell were originally brought into circulation by Sporeworks.

On sterilised grass seed, rice and millet the 'A' strain produces large sclerotia, hardened mycelial structures that contain psilocybin and psilocin. Sclerotia usually enlarge until about 3 months after inoculation after which they can be harvested.
Mushroom production is limited and few mushrooms can be harvested. However, large sclerotia form in the casing soil of fruiting trays. If you are interested in growing mushrooms of the *Psilocybe mexicana* we recommend you look at the 'B' strain.
The 'B' strain does not produce sclerotia in uncased substrates, only in the casing layer of fruiting trays. This strain does produce massive flushes of mushrooms.
The mycelium of the 'A' strain forms typical rings of sclerotia on malt extraxt agar. Sclerotia can be planted and mushrooms can form directly from them.
In our standard jars with 110 grams of grass seed and 180 ml of water it produces an average of 90 grams fresh weight in 3 months. This species can also be succesfully grown in autoclavable spawnbags.

Experiments have yet to determine the optimal substrate for this strain but so far grass seed, millet and rice have proven to be useful. Undoubtly there are more substrates that support sclerotia formation better than those three.

This species was highly sought after for years because of it's sclerotia forming abilities. The two mexicana strains we sell were originally brought into circulation by Sporeworks.

This strain gives out abundant amount of mushroom and sclerotia on cased substrates of grass seed. The strain does not produce sclerotia invitro.
If you are interested in growing sclerotia in vitro, we recommend you to look at the "A" strain. The "A" strain produce a lot of sclerotia on uncased substrates but gives off little of mushrooms.
This mushroom is weak reproducer, to obtain good spores, we suggest you to wait untill caps will curl up completely.

It differs from all the species of the Section in its small cheilocystidia, smaller even than those recently described in the same Section (Guzmán, 1982; Cifuentes & Guzmán, 1981) from Mexico.

Stem/Stipe: 5-9 (-12) x (0,15) 0,2-0,3 (-0,4) cm, cylindrical, often with a somewhat scabrous surface, Usually lank, less commonly robust, short and distinctly curved and not enlarged at the base. with remains of a partial veil building a fibrillous annular zone. Whitish rhizomorphs at base fibrillating into woody debris Whitish and off white, rarely whole stipe blue-green tinged. Stains blue when bruised.

Microscopic feat.:

Basidio/Spores: (10) 11-13,5 (-14,8) x (6-) 6,2-7,0 (-7-8) µm. Brown, ellipsoid, broadly ellipsoid or elongated and somewhat lemon-shaped. Sporeprint purple-brown.

Habitat: In groups on woody debris in deciduous or mixed forests, in grass on woody debris in soil and underbrush of *Utica* or *Rubus*, often in localities disturbed by human influence with accumulation of woody waste.

Distribution: It has been only reported from five distinct localities int he Czech Republic, 230-700 m above sea level.

Season: Late September to end of November, or mid December depending on warm autumn months.

Dosage: Unknown at present.

Comment: This fungi according to the author smells sweet and spicy not farinaceous and taste rather bitter. 9 specimens of this mushroom from two localities in the Czech Republic were analysed for psilocin/psilocybin content and showed a high concentration of psilocin as compared to a low content of psilocybin. Higher concentrations of indole derivatives were found in fruitbodies obtained from lower elevations. This is the third bluing *Psilocybe* described in the Czech Republic.

Studied material: MEXICO: State of Chiapas, road Ocozocuatla to Apic-Pac (Malpaso Dam), Laguna Bálgica, Sept. 26,1993, Guzmán 30723 (Holotype, XAL).

Discussion: Etymology - this species is named in honor of Dr. Meinhard Moser (Innsbruck).
This species belongs to Sect. Zapotecorum because of its thin-walled spores and for the bluing reaction. The peculiar pleurocystidia, the two types of cheilocystidia, the pseudorrhiza, as well as the smaller spores, separate *Psilocybe moseri* from all the species considered by Guzmán *et al.* (1988) in this section. *Psilocybe moseri* is the species with the smallest spores in the section and the only tropical one (the others are from the subtropical highlands or from coniferous forests), which confirms the observations by Guzmán (1979), that the tropical species of *Psilocybe* have small spores in comparation with the alpine species. For instance, *Psilocybe uxpanapensis* Guzmán from the tropics, has spores that are (5-) 5.5-6.5 (-7.5) µm long as compared with *Psilocybe aztecorum* from alpine regions with 12-14 µm long spores.

Habitat: Gregarious to cespitose in muddy and swampy soils on the walls of ravines in fir (*Abies*) and pine (*Pinus*) woodlands. Found August through September in Mexico (state of Mexico).

Comment: Potently active, judging by the strength of the bluing reaction. The name *Psilocybe wassoni* was preempted by Smith and Singer's publication of the name just 24 days prior to the publication of Heim and Wasson's (1958) masterpiece, and given the international rules governing nomenclature, the name first published presides. Since may of Singer's Mexican contacts were provided, in good faith, by Heim and Wasson, this event created a rift between two schools of mycologists that persisted for several decades. Heim and Hofmann (1958) found 0.02% psilocybin and 0.01% psilocin in seven-month-old specimens. Undoubtedly, fresh specimens are many orders of magnitude stronger.

Psilocybe naematoliformis

Psilocybe naematoliformis Guzmán (1979)

synonyms:
Naematoloma naematoliforme (Guzmán) Guzmán (1980)
Hypholoma naematoliformis (Guzmán) Guzmán (1999)

Description: *Psilocybe naematoliformis*, is a species of fungus in the mushroom family Strophariaceae. It is a psilocybin mushroom, having psilocybin and psilocin as the main active hallucinogenic compounds.
The species was originally found by mycologist Gastón Guzmán in a tropical rainforest at Uxpanapa Region, in the State of Veracruz in southeastern Mexico; he reported the finding in a 1979 publication, and called the fungus *Psilocybe naematoliformis*. Guzmán later considered species with chrysocystidia (cystidia whose contents contain a distinct refractive yellow body, that become more deeply yellow when stained with ammonia or other alkaline compounds) to be separate from *Psilocybe*, and transferred the species first to Naematoloma in 1980, and then later to Hypholoma in 1999. In 2004, Guzmán revised his opinion again, and considered the species more suitably placed in *Psilocybe*.
Psilocybe naematoliformis is in the section Neocaledonicae, a group of related tropical and subtropical species in the *Psilocybe* genus; other members of the section include *Psilocybe aequatoriae* (Ecuador), *Psilocybe neocaledonicum* (New Caledonia), and *Psilocybe neorhombispora* (Mexico).

Macroscopic feat.:

Cap/Pileus: 1-3 cm (0.4-1.2 in) in diameter, bell-shaped to subumbonate, smooth, and slightly slimy but soon dry. The color may range from a pale orange-brown to a deep rusty brown. It is hygrophanous, fading to buff; the color is blackish brown when dry, and slightly translucent-striate when wet. Like other hallucinogenic psilocybes, it stains blue when bruised or injured.
Gills/Lamellae: Adnate in attachment to the stem, or may be notched at the point of attachment (sinuate). They are narrow, and brownish violet to dark violet, with whitish edges.
Stem/Stipe: 3.5-5.5 cm (1.4-2.2 in) tall by 1-3 mm thick, subequal, flexuous, and hollow. The color of the stem is reddish-brown or brownish; it is densely covered with silk-like fibers, and tufts of soft woolly hairs. The veil does not form an annulus.
Odor: Slightly farinaceous, like grain, and the taste of this species has been described as slightly bitter.

Microscopic feat.:

Basidio/Spores: (3.8)4.9-5.5(6.6) by (3.3)4.4-5(6.6) by 3.8-4.4 µm, sublentiform (shaped somewhat like a biconvex lens) in face view or roughly elliptic in side view, with an inconspicuous hilar appendage. They have a distinct germ pore in the base, and are smooth and thick-walled.
Basidia: The spore-bearing cells in the hymenium, are 12-19 by 4.4-5.5 µm, and hyaline.
Pleurocistidia: (Cystidia on the gill face) are 15-29 by 5.5-8.8 µm; clear, gray or brown in color, fusoid-ventricose to mucronate, sometimes with a median constriction, similar to the species *Psilocybe subaeruginosa* Clel. from Australia.
Cheilocystidia: (Cystidia on the gill edge) are 12-28 by 5.5-7.7 µm, hyaline, very numerous, ventricose, mucronate or fusiform-lanceolate, often forked.

Habitat: *Psilocybe naematoliformis* is found growing in small groups, in tufts or clumps, on disturbed places of the virgin tropical rain forest; it grows in soil with a few herbaceous plants. This species was originally found in Mexico, State of Veracruz, Uxpanapa region.

Psilocybe natarajanii

Psilocybe natarajanii Guzmán

synonyms:

Psilocybe aztecorum var. *bonetii* (Guzmán) Guzmán sensu Natarajan & Raman.

This species differs from *Psilocybe aztecorum* var. *bonetii* known only from Mexico, in the size and form of the pleurocystidia. *Psilocybe natarajanii* has mucronate pleurocystidia 21-28 x 7-10 µm, instead of the 20-45 x 5-8 µm, lageniform pleurocystidia with a long neck found in the Mexican fungus. *Psilocybe natarajanii* is known only from the type locality. This species is close to *Psilocybe pseudoaztecorum* (Natarajan & Raman, 1985) (= *Psilocybe aztecorum* var. *aztecorum* sensu Natarajan & Raman, 1983), but differs in the smaller spores, 12.5-17 µm long in Psilocybe pseudoaztecorum vs. 10-12.5(-14) µm in *Psilocybe natarajanii*. The above description is compiled from Natarajan & Raman (1983), because no herbarium material was studied.

---

synonyms:
Psilocybe neocaledonica Guzmán & Horak

Naematoloma neocaledonica (Guzmán & Horak) Guzmán

Macroscopic feat.:

Cap/Pileus: 8-11 mm broad, conico-papillate to subconvex, deep brown, fading to pale orange-red or stramineous when drying, not viscid, densely covered with concolorous fibrillose squamules especially towards the striate margin, occasionally also with white minute squamules from the veil along the margin.
Gills/Lamellae: Broadly adnate to subdecurrent, often with short tooth, deep chocolate brown to violaceous brown, edges whitish and fimbriate.
Stem/Stipe: 12-15 by 1-1.5 mm, cylindrical or rarely subbulbous, pale orange brown, covered with concolorous or whitish fibrils of the veil, but distinct cortina zone or anulus absent, hollow, single.
Context: Whitish.
Odor: And taste not distinctive.

Microscopic feat.:

Basidio/Spores: (5) 5.5-6 (-6.5) by 5.5-6 (-6.5) na 4-4.5 µm, rhombic or globose-rhombic, subelliptical in side view, membrane yellowish brown, with broad truncate germ pore.
Basidia: 16.5-20 by 4-6.5 µm, 4-spored, hyaline (KOH), subcylindric with slight median constriction.
Pleurocistidia: 22-28 by 11-14.5 µm, ventricose-rostrate, apical beak measuring 2-5.5 by 1.5-3.5 µm, hyaline or brownish (KOH), many with hyaline to yellowish refractive pigment-body of irregular shape (like chrysocystidia).
Cheilocystidia: 17-27 by 4-6.5 µm, polymorphous (fusiform, subventricose-rostrate or sublageniform), forming dense and sterile turf on gill edge, hyaline (KOH), rarely with hyaline apical oil drop.

Trama: Regular, hyaline to pale orange brown (KOH), pigment irregularly encrusting the membranes (0.5-1.5 µm diam.).
Epicutis: Consisting of hyaline to yellowish-brownish subgelatinous parallel thin hyphae.
Hypodermium: Of elongate hyphae (5-15 µm diam.) with hyaline to brownish membranes (- 2 µm diam.). Clamp connections present.

Habitat: Gregarious on rotten wood, sticks and plant debris in tropical forest at about 1000 m a. s. l. Known from type locality only.

Studied material: NEW CALEDONIA, Mt. Mou, N of Paita; 22. II. 1977, leg. HORAK (Holotype ZT, 77/161; isotype ENCG).

Discussion: The pleurocystidia and cheilocystidia of this species are similar to the ones observed in *Psilocybe nematolomiformis* Guzmán (1977), described from tropical rain forest in Mexico, differ, however, in size and shape. Furthermore, the pileus of the Mexican species is glabrous. *Psilocybe neocaledonica* is also close to *Agaricus* (*Naucoria*) *lonchophorus* B. & Br. from Ceylon. Upon examining the type material of this species (K) by one of the authors (HORAK), only hyaline pleurocystidia have been found and chrysocystidia-like cystidia are absent. The non-cellular structure of the subcutis or hypodermium in combination with the rhombic spores are distinctly separating this New Caledonian species from taxa of the genus *Naematoloma* Karsten. It is possible that this new species is an hallucinogenic fungus since it has close taxonomic relationships with hallucinogenic species of the Stirps Yungensis.

Psilocybe ovoideocystidiata

Psilocybe ovoideocystidiata Guzmán et Gaines

Macroscopic feat.:

Cap/Pileus: 10-45 mm in diameter, brown with a sticky surface when moist drying to a pale bluish grey to white.
Stem/Stipe: 25-90 mm, white to buff with a distinct but fragile membranous annulus, base tenaciously attached to substrate with thick white rhizomorphs.
Gills/Lamellae: Subadnate, brownish.

Microscopic feat.:

Basidio/Spores: 8-10 by 6-7 µm, subrhomboid to rhomboid.

Habitat: Climate temperate. Hardwood logs and debris.

Comment: Previously misidentified as *Psilocybe caerulipes*. Closer examination reveals that the Bethany collection is most likely *Psilocybe ovoideocystidiata*, which agrees with the identification proposed by Psilocybe expert, Gastón Guzmán. *Psilocybe ovoideocystidiata* is only known from Ohio, Pennsylvania and West Virginia.
This was the only species we provided that had not been directly assessed by our staff. It is our policy not to accept spore products from outside sources in order to maintain tight quality control and correct identification. Due to the rarity and exceptional documentation of the samples we made an exception. Unfortunately, without actual specimens to examine, staff misidentified the species. At the time we were unaware of the existence of the newly described *Psilocybe ovoideocystidiata* and made our identification based primarily on the location of the initial collection. We could not have guessed that another species would be found in an area previously only known for a single, native and active *Psilocybe* that shares the same habitat.

Studied material: PAPUA NEW GUINEA, Eastern Highlands: Mt. Michael, Frigano, Hut Track; 6. XII. 1971, leg. HORAK (Holotype ZT, 71/385; isotype in ENCB). - Kassem Pass; 13. XII. 1972, leg. HOKAK (ZT, 72/726).

Discussion: This species reminds of the hallucinogenic *Psilocybe caerulescens* MURR., reported from the SE of the United States and Mexico (SINGER & SMITH, 1958). The shape and size of the cheilocystidia, however, are distinctly separating the two species.

Psilocybe pelliculosa

Psilocybe pelliculosa (A.H.Sm.) Singer & A.H.Sm. (1958)

---

synonyms:
Psathyra pelliculosa A.H.Sm. (1937)

Macroscopic feat.:

Cap/Pileus: 0.5-2 (3) cm broad. Obtusely conic, becoming conic-campanulate with age. Margin translucent-striate and generally not incurved in young specimens. Chestnut brown when moist, then dark dingy yellow to pale yellow in drying (hygrophanous), often with a pallid band along the margin, and frequently tinged olive green in patches. Surface smooth, viscid when moist from a separable gelatinous pellicle. Flesh thin, pliant, and more or less concolorous with the cap.
Gills/Lamellae: Attachment adnate to adnexed, finally seceding, close, narrow to moderately broad. Color dull cinnamon brown, darkening with spores in age.
Stem/Stipe: 60-80 mm long by 1-2.5 mm thick. Equal above, and slightly enlarged at the base. Surface is covered with appressed grayish fibrils, and powdered at the apex. Whitish to pallid to grayish more brownish toward the base, blue green where bruised or with age. Flesh stuffed with a tough pith. Partial veil thin to obscure or absent.

Microscopic feat.:

Basidio/Spores: Spores purplish brown in deposit, subellipsoid to subovoid, 9-13 by 5-7 µm.
Basidia: 4-spored.
Pleurocistidia: Absent.
Cheilocystidia: 17-36 by 4-7.5 µm, fusiform to lace-shaped, with an elongated neck 1.5-2 µm thick.

Habitat: Scattered to gregarious to cespitose on well-decayed conifer substratum, in mulch, or in soil rich in lignin. Often seen along paths in conifer forests and along abandoned logging roads that are actively being recaptured by alders and firs. Found in mid-to-late fall to early winter throughout the Pacific Northwest and Northern California.

Comment: Active, although comparatively weak, containing up to 0.41% psilocybin, no psilocin, and 0.04% baeocystin, as reported by Beug and Bigwood (1982b) and Repke et al. (1977). *Psilocybe pelliculosa* is nearly identical with *Psilocybe silvatica*, and is distinguished from it by the length of the spores. The conic-shaped cap, the gregarious nature of their fruitings, the fibrillose patches on the stem, and the bluing reaction at the base of the stem are some of the most distinctive features of this species. See also *Psilocybe silvatica* and *Psilocybe washingtonensis*. This mushroom has a general resemblance, especially at a distance, to *Hypholoma dispersum (=Naematoloma dispersum)*. When my kids were toddlers, I would take them mushroom hunting in the Olympic Peninsula. On one November trip, after parking the car, we strolled up an abandoned logging road. Coming down the road were two pot (edible mushroom) hunters. When I asked if there were any good mushrooms up there, they replied, "There's nothing of interest." Less than fifty yards later, we found several thousand *Psilocybe pelliculosa*. The patch looked like a well-organized army of mushrooms, standing tall and proud. The pot hunters had walked right through the multitudes, unaware of the potential for a life-changing experience.

Macroscopic feat.:

Cap/Pileus: 0.5-2.5 cm. Convex to slightly subumbonate at first, soon expanding to broadly convex to nearly plane, often with an undulating margin and subumbonate. Surface smooth, viscid when moist and translucent-striate along the margin, which can be decorated with fibrillose remnants of the partial veil. Chestnut brown to reddish brown, lighter along the margin, hygrophanous, fading in drying to straw yellow or dingy yellow.
Gills/Lamellae: Attachment adnate to adnexed, or sinuate. Dingy vinaceous brown, becoming dark purplish brown with spore maturity.
Stem/Stipe: 15-50 mm long by 1-1.5 mm thick, typically enlarging towards the apex, then narrowing, and enlarging at the base. Rigid, hollow, and covered with patches of fine grayish fibrils, darkening upwards. Partial veil cortinate, deteriorating with age and leaving remnants.

Microscopic feat.:

Basidio/Spores: Violet blackish brown in deposit, subrhomboid in face view, subellipsoid in side view, 6-8 by 4-5.5 µm. Pale yellowish brown to tan with spore maturity.
Basidia: 4-spored.
Pleurocistidia: Absent.
Cheilocystidia: 16-28 (33) by 4-7 µm, fusoid to sublageniform with short necks 3.3-4.4 µm thick.

Habitat: Solitary to gregarious, sometimes subcespitose in disturbed soils, soils rich with woody debris, often at field-forest (conifer) interfaces. Common in Europe, also reported from Canada, Greenland, and the northern United States, including Alaska. This mushroom has been collected as far south as Santa Barbara. Often fruits in the summer through early fall.

Comment: Not known to be active; not yet analyzed. The silvery sheath of fibrils from a darkening base is a feature that stands out for this mushroom, and is reminiscent of *Psilocybe crobula*, *Psilocybe inquilina* and to a lesser degree *Psilocybe montana*.

Psilocybe pintonii

Psilocybe pintonii Guzmán

Macroscopic feat.:

Cap/Pileus: 15-40 mm diam., subconvex co subumbonate or subpapillate, sometimes irregularly lobulate, eventually appianate or subconcave, smooth, but when young covered by white fibrils from the veil; sometimes slightly rimose, lubricous to dry, slightly transparently striate when moist, hygrophanous, brownish to orange brown or chocolate brown, fading to a dirty yellow.
Gills/Lamellae: Sinuate or adnate, brownish to gray violet, thick with whitish to concolorous edges.
Stem/Stipe: 25-60 x 3-5 mm, cylindrical, hollow, whitish to subconcolorous with the pileus, covered toward the base by floccose white veil fibrils; base remaining somewhat blackish in dried specimens. Both pileus and stipe stain green-blue when injured. Veil well developed when young but absent in the adult stage.
Context: Whitish to brownish, fleshy in the pileus, fibrous-hard in stipe; staining blue when cut, with farinaceous odor and taste.

Microscopic feat.:

Basidio/Spores: (6-) 6.6-7.7 (-8.8) x (3.3-) 4-4.5 µm, ellipsoid or subelliptic, somewhat subrhomboid in face view, thin walled, smooth, brownish yellow.
Basidia: 16-22 x 4.4-8 µm, four-spored, cylindric-pyriform, sometimes sinuos-pyriform.
Pleurocistidia: Absent.
Cheilocystidia: 17-20 x 4-7 µm, hyaline, ventricose-fusoid, lageniform, irregularly ventricose with constrictions or branched or with capitate to subcapitate apex, mixed with basidia in different stages of deformation.
Subhymenium: Brownish without incrusting pigment, but with thick irregular walls in the hyphae; these 6-25 µm.
Epicutis: Subgelatinized, formed by hyaline elongated and parallel hyphae 3-5 µm broad.
Hypodermium: With hyphae with reddish brownish 4-8 µm broad.

Habitat: Solitary or gregarious on soil without herbaceous vegetation, in páramos with *Espeletia*, at 3450-3600 m elevation.

Studied material: COLOMBIA, Cundinamarca Dept, Páramo de Palacio, Hacienda La Siberia, road La Calera to La Mina, near the branch to Rincón del Oso, Aug. 20, 1964, Guzmán 9160 (ENCB); July 23, 1971, Guzmán 9762 (Holotype COL; Isotype ENCB).

Discussion: This species is close to *Psilocybe zapotecorum* Heim and *Psilocybe muliercula* Sing. & Smith, and certainly belongs to the same group, but the special cheilocystidia separate it well from the other species. Because of the bluing reaction and the farinaceous odor and taste, this is probably a hallucinogenic species, but there is no information about its use. The same situation holds true for *Psilocybe columbiana*.

Discussion: This species belongs to Sect. *Cordisporae* Guzmán by virtue of their smaller rhomboid spores, bluing feature and subtropical habitat. It is close to *Psilocybe subtropicalis* Guzmán, from Mexico and Guatemala, by the branched cheilocystidia, but that species has spores (5.5-) 6.5-7 (-8) µm long and collybioid habit (Guzmán, 1995). *Psilocybe plutonia* differs with pleurocystidia broadly ventricose, ventricose-mucronate or obpyriform, 17-26 (-30) x 9-12 µm (Guzmán, 1983, 1995).

---

synonyms:
Psilocybe pseudocyanea (Desmazieres: Fries) Noordeloos

Macroscopic feat.:

Cap/Pileus: 1-3 cm, conic-convex, expanding to acutely to bluntly umbonate, whitish with azure to bluish green tinges, fading to straw or cream colored. Surface viscid from a separable gelatinous pellicle. Margin adorned with remnants of the partial veil. Flesh bluish green, fading to azure, then pale bluish green and eventually straw colored.
Gills/Lamellae: Attachment adnate, pale fawn to purplish, with toothlike edges.
Stem/Stipe: 35-70 mm long by 2-5 mm thick, equal, slim, flexuous, bluish green to azure blue to straw colored, soft, easily breaking, pruinose-flocculose particularly towards the apex. Partial veil membranous, leaving a membranous annulus, degrading into an annular zone.

Microscopic feat.:

Basidio/Spores: Purplish brown in deposit, ellipsoid, 7-9 by 4-5 µm.
Basidia: 4-spored.
Cheilocystidia: Capitate-clavate to lageniform capitate, 24-44 by 4-8 µm by 4-5 at apex when narrowing, or 6-12 µm when swollen.

Habitat: Prefers tall grass in wetlands, marshes, and meadows, or tall shrubs along trails at field-forest interfaces. Known from the British Isles, much of northern Europe, and the Pacific Northwest. Probably more widely distributed.

Comment: Activity unknown. Due caution is advised. *Psilocybe pseudocyanea* is closely related to *Psilocybe aeruginosa* and *Psilocybe caerulea*. All of these species were formerly placed in the genus *Stropharia* but recently transferred to *Psilocybe* by Noordeloos (1995). The smaller spores, soft stem, and wetland habitats are classic features. The edibility of this species is not well documented. The bluish color and its close taxonomic relationship to active species makes *Psilocybe pseudocyanea* a likely candidate for activity. However, caution is always recommended with these less-studied species that lack an experiential history.

Psilocybe quebecensis

Psilocybe quebecensis Ola'h & R. Heim 1967

Macroscopic feat.:

Cap/Pileus: 1-3.5 cm broad. Nearly hemispheric at first, soon expanding to convex, then becoming broadly convex to plane, and without an umbo. Margin incurved at first and usually not markedly undulated; translucent-striate when moist. Pale straw yellow and often with brownish or tawny hues, becoming more grayish in drying. Bruising bluish when touched or disturbed. Surface smooth, becoming finely wrinkled with age, and viscid when moist. Flesh whitish.
Gills/Lamellae: Attachment adnate, thin, moderately broad to swollen in the middle. Becoming very dark chestnut brown at maturity, and usually somewhat mottled, with the edges remaining whitish.
Stem/Stipe: 20-35 (45) mm long by 1-2.5 mm thick. Brittle, tough, and fibrous. Slightly enlarged at the apex and flared at the base, which is often furnished with rhizomorphs. Yellowish tawny, drying to a distinct grayish yellow, becoming bluish where bruised. Partial veil cortinate, fugacious, and soon disappearing.

Microscopic feat.:

Basidio/Spores: Spores purplish brown to black in deposit, ellipsoid to subovoid in side and face view, some spores mango shaped, 8-14 (16) by 6-8.8 µm.
Basidia: 4-spored.
Pleurocistidia: Present, 12-35 by 9-15 µm, very distinctive by their swollen apices, as in *Psilocybe cubensis* and *Psilocybe cyanescens*.
Cheilocystidia: 18-36 by 5.5-10 µm, fusoid-ampullaceous with an extended neck, 2-3.3 µm thick.

Habitat: Grows in sandy soils, particularly in outwashes of streams, and in the decayed-wood substratum of alder, birch, fir, and spruce in the late summer and fall. Reported from Quebec, specifically in the Jacques Cartier river valley.

Comment: Moderately active according to Ola'h and Heim (1967). *Psilocybe quebecensis* is a classic flood-plain species and is probably more widely distributed than presently reported. This species is not well known to Quebec residents, and I suspect that naturalized colonies could easily be established by those wishing to have *Psilocybe quebecensis* growing in their backyard. See also *Psilocybe caerulipes* and *Psilocybe baeocystis*.

Psilocybe samuiensis

Psilocybe samuiensis Guzmán, Bandala & Allen

Macroscopic feat.:

Cap/Pileus: 7 to 1.5 cm. Convex to conic-convex to campanulate, often umbonate with a small papilla. Translucent when moist, striate margin in young, and with a separate pellicle. Hygrophanous and fading to straw-yellow in drying.
Gills/Lamellae: Adnate and clay colored, than violaceous brown to chocolate-violet with whitish margins.
Stem/Stipe: 40 to 60 mm. long by 1-2 mm thick. Whitish to yellowish and covered with fibrils. Enlarged at base. Partial veil cortinate leaving a superior fibrillous annular zone that soon disappears.

Microscopic feat.:

Basidio/Spores: 9.3-13 x 5-7 µm. Sporeprint - chocolate to purple-brown.
Basidia: 4-spored.
Pleurocistidia: Scattered and ventricose towards the base.

Habitat: Grows in well manured clay-like soils in rice paddies and open grassy areas.

Distribution: Koh Samui Island in the Gulf of Thailand and surrounding areas. Ranong Province, Thailand and at Angkor Wat, Cambodia.

Season: Late may through September and possibly into October.

Dosage: 15-20 fresh mushrooms

Comment: So far this mushroom has only been found four times, fruiting in rice paddies from two locations on Koh Samui Island in the Gulf of Thailand. First in 1991 by John W. Allen in rice paddie fields near the Muslim village of Ban Hua Thanon, Koh Samui. Ten years later, a 2nd collection was gathered with Chief Ill Eagle, Travis Canaday, Nataya and Mike Acevedo, about 100 meters past where the first collection was found ten years earlier.
In 2003, JWA found 8 specimens in a second location a few miles down the road in the rice paddie fields of Na Muang, Koh Samui. And again in 2004, numerous collections were gathered from that same field during two separate fruitings in June and July of 2004. Its fruiting run is from 5 to 7 days and then they are gone from the fields.
Most likely it is probable that this species also fruits in other locations in southern Thailand and possibly Malaysia. It is not, as reported by http://www.petfungus.com found in Eastern Oregon. This species is closely related to *Psilocybe mexicana* Heim Heim and is macroscopically similar to *Psilocybe semilanceata* and is the first species found outside of Mexico directly related to *Psilocybe mexicana* Heim, That latter species is ceremoniously used by native Americans in Mesoamerica.

Psilocybe sanctorum was known only from the type locality in Mexico, in the State of Mexico, in grassland on the border of a *Pinus-Quercus-Populus* forest (Guzmán, 1982). It is now recorded for first time from the State of Veracruz [Chacón 2529 (XAL), 5 km W from Coatepec, Aug. 22, 1984, in a subtropical (mesophytic) forest]. This material differs from the type by the pileus which is not so papillate. This demonstrates the variation of the basidiomata in this species, a feature typical of several other species of Sect. Zapotecorum.

Macroscopic feat.:

Cap/Pileus: 1-4 cm broad. Obtuse to hemispheric to convex and finally broadly convex in age. Occasionally with an umbo. Light yellow to deep straw yellow when fresh, not hygrophanous. Surface smooth, viscid to extremely viscid to glutinous from a separable gelatinous pellicle. Flesh form, watery buff, not bruising.
Gills/Lamellae: Attachment adnate, broad, close to subdistant, with one to two tiers of intermediate gills. Grayish when young, becoming purplish brown with spore maturity, edges remaining pale to whitish.
Stem/Stipe: 30-120 mm long by 2-5 mm thick. Equal to slightly enlarged downwards. Surface below annular zone, whitish to nearly concolorous with cap, viscid to extremely viscid to glutinous in the lower two thirds of the stem. Partial veil glutinous, leaving an annular zone of fibrils, soon darkened. Flesh stuffed with a yellowish pith at first, and becoming hollow with age. No bruising reaction.

Microscopic feat.:

Basidio/Spores: Dark purplish brown in deposit, ellipsoid, 15-19 by 8-10 µm.
Basidia: 4-spored.
Cheilocystidia: Present, narrowly fusoid-ventricose with a long, flexuous neck, 26-38 by 6-9 µm.
Pleurocistidia: Difficult to find, 32-46 by 9-14 µm.

Habitat: Single to gregarious on cow or horse dung in the spring, summer, and fall. Widely distributed throughout North America and much of the temperate regions of the world.

Comment: Not active. *Psilocybe semiglobata*, formerly known as *Stropharia semiglobata*, is included here because this mushroom is prolific in habitats also frequented by the active *Psilocybes* and *Panaeoli*. I have often found *Psilocybe merdaria*, *Psilocybe coprophila* and *Panaeolus papilionaceus* sharing the same habitat with *Psilocybe semiglobata*. The natural affinities between these Psilocybes is obvious to all who have collected them. The uniquely glutinous veil disthinguishes this species from close relatives.

Gills/Lamellae: The gills are Adnate light grayish brown at first, turning dark purple as the spores mature.
Stem/Stipe: 15-20 x 2 mm, hollow, has an equal width, and is white with whitish or brownish floccose scales, drying to a reddish brown. It stains blue near the base.

Microscopic feat.:

Basidio/Spores: 8-10 x 5,7 µm, subovoid to ellipsoid, thick-walled, and yellowish brown to dark purple brown in deposit.
Basidia: 4-spored.
Cheilocystidia: Sublageniform and 24-30 x 6-8 µm. No pleurocystidia have been observed. Clamp connections are present.

Habitat: Gregarious in small groups among shrubs on a creek bank.

Not common. Sporocarps grow from summer to autumn with peak in late autumn, singly or groups of several, terrestrial or on grass remnants, in nutrient-poor pastures, meadows or other grassy terrains, never on fresh manure, if accidentally on cattle manure, then on very old one.
Pileus hygrophanous, olive-pale brown when moist, also with dark olive or livid-green spots, particularly at the edge, pale straw-coloured when dry, ochraceous; 5-15(20) mm in diameter, 6-15(20) mm high, initially obtusely conical and usually with a distinct papilla, acutely umbonate, with age conical to campanulate, but never plane; surface smooth, when moist lubricous, slightly viscid; margin initially incurved, later plane or decurved, slightly translucent-striate when moist, in very young specimens visible whitish fibrils of the veil connecting the pileal margin with the stipe.

Psilocybe semilanceata „Gigant“

There are 2 valleys high in the hills of Spain where Ignacio finds the p. semilanceata's (a.k.a. liberty caps). One of those valleys produces some very large and potent semi's that grow on horse dung and straw. The other valley produces your typical small sized potent semi.
To date, there are no known cases of the semilanceata successfully being cultivated indoors. These pics are kind of inspiring because there growing on straw. Perhaps time to rethink that strategy. We now have spore prints of the giant straw loving *Psilocybe semilanceata* from Spain as well.

Agaricus squamosus
Geophila squamosa
Hypholoma squamosum
Naematoloma squamosum
Psalliota squamosa

Stropholoma squamosum

Macroscopic feat.:

Cap/Pileus: 3-8 cm broad. Conic or obtusely conic when young, with an incurved margin soon becoming broadly campanulate to convex, and often with a conic umbo. Viscid when moist from a separable gelationous pellicle, but soon drying. Yellowish brown to orangish brown overall. At first adorned with small squamules (scales) along the margin, but soon smooth and free of veil remnants. Flesh relatively thin and watery brown when wet.
Gills/Lamellae: Attachment adnate to uncinate, close to subdistant, moderately broad, with two to three tiers of intermediate gills inserted. Pallid bluish gray, then dark grayish brown to purple brown when fully mature.
Stem/Stipe: 60-120 mm long by 4-8 mm thick. Equal to slightly enlarged and curved at the base, hollow, and somewhat fragile. Whitish towards the apes and sordid brown to dense buff below the annulus. Surface covered with evanescent pallid to brownish recurved scales, often with orange-buff rhizomorphs protruding about the base. Partial veil membranous, fragile, leaving a superior membranous annulus, striated on the top side, often hanging broken around the stem or entirely absent in age.

Microscopic feat.:

Basidio/Spores: Dark grayish violet brown in deposit, subellipsoid, 11-15 by 7-8 µm with a central germ pore.
Basidia: 4-spored.
Cheilocystidia: 36-66 by 3.3-6 µm, filamentous to sublageniform, with an apex adorned with a glutinous mass.
Pleurocistidia: Absent.

Habitat: Solitary to scattered in the late summer and fall in meadows and mixed conifer and alder woods. Known from the Pacific Northwest, Minnesota, and California. It is likely this species is widely distributed across the continent.

Comment: There are conflicting reports on the edibility of *Psilocybe squamosa*; caution is definitely recommended. Once a *Stropharia*, this species lacks the chrysocystidia once typical of that genus. Both the squamules of the cap and the annulus are temporal features, and can soon disappear after heavy rains. See also *Psilocybe thrausta*, which is very similar but differs in the reddish coloration of the caps.

Macroscopic feat.:

Cap/Pileus: 0,5-3 cm broad, conic at first, expanding to convex, campanulate, and eventually broadly convex, and typically not sharply umbonate but may have a low umbo. Surface smooth, translucent-striate near the margin, which may have slight remnants of the veil and viscid when moist from a separable gelatinous pellicle. Dark grayish brown to cinnamon brown, fading to straw or light yellow in drying. Flesh sometimes bruising bluish when injured.
Gills/Lamellae: Attachment adnate, sometimes subdecurrent, and tearing free from the stem in drying. Chocolate brown with whitish edges when mature.
Stem/Stipe: 40-70 (130) mm long by 2-3 mm thick. White to yellow to yellowish brown. Equal, straight to flexuous, typically tough, cartilaginous, and decorated with fibrillose patches, veil remnants, and basal mycelium that can bruise bluish. (Base is not adorned with cordlike rhizomorphs.) Partial veil thinly cortinate, fragile, and rarely leaving an annular zone on the upper regions of the stem.

Microscopic feat.:

Basidio/Spores: Spores dark purple brown in deposit, subellipsoid to suboblong 10-12 by 5.5-8 µm.
Basidia: 4-spored.
Pleurocistidia: Absent.
Cheilocystidia: 21-45 by 7-10 µm, lageniform with an extended neck 2-3.5 µm thick.

Habitat: Fruits in the late summer to fall in the Pacific Northwest, England, northern and central Europe (Czech Republic, France, Germany, Holland, Slovakia, Sweden), Siberia and Chile. Typically found in rich, grassy areas such as lawns, along roadsides, and in fields - but not on dung, although common in fields with and without manure.

Comment: Chemical analysis not available. Estimated to be moderately active to potent, judging from personal bioassays, and probably low in psilocin, because of the limited bluing reaction. *Psilocybe strictipes* is a slender, grassland species, thought to be an intermediate form, bridging *Psilocybe semilanceata* and *Psilocybe pelliculosa*, two taxa that are very similar in general appearance except for habitat preferences and/or microscopic details. *Psilocybe strictipes* has had a very confused history. Guzmán (1995), following Redhead (1985) and Watling and Gregory (1987), attempted to clear up the long-standing confusion surrounding this species and its well-known synonym, *Psilocybe callosa*. (The original *Agaricus callosus* Fr. is not related to the mushroom described here and is actually synonymous with *Panaeolus papilionaceus* Bull. ex: Fr. Quelet.).
The modern concept of *Psilocybe callosa* became subordinate to a new taxon, which Singer and Smith (1958a) originally proposed as *Psilocybe strictipes*. Guzmán (1983) had made *Psilocybe strictipes* subordinate to *Psilocybe callosa* in his monograph. Upon reevaluation, Guzmán (1995) reaffirmed *Psilocybe strictipes* as the proper name. Mixed collections resulted in this species being further confused with *Psilocybe baeocystis*, to which it bears little resemblance. Furthermore, the preferred habitat for *Psilocybe strictipes* is grasslands or rich soils, not the woodlands that Singer and Smith (1958a) had described. Their line drawings of *Psilocybe strictipes* show two distinct forms: one mycenoid resembling the closely related *Psilocybe semilanceata*, and an isolated drawing, more collyboid in shape, showing a mushroom atypical to the first form. Guzmán (1983) writes that the specimen used by Smith to make the line drawing was actually *Psilocybe baeocystis*. Additionally, in their original description they indicate that the collection number assigned to the original type was erroneous, which perhaps related to the original confusion and the two decades of confusion that followed. Virtually all the field guides published since 1958, including mine (1978), erroneously describe *Psilocybe strictipes*.
For most field hunters, the grassland habitat narrows the field of candidate possibilities. The absence of sharp umbo and its thinly fleshed cap are two macroscopic features that delineate this species from its closest ally, *Psilocybe semilanceata*, with which it is often confused. Guzmán (1983, 17) noted that, "the form of the pileus is of taxonomic value in *Psilocybe*. *Psilocybe semilanceata* is distinguished from *Psilocybe callosa* (=*Psilocybe strictipes*) on the papilla in the first and in the convex to the more or less subumbonate pileus in the latter."
With many grassland species, the length of the stem is usually a direct response to the height of the grass through which its arises. The stem base is typically tightly attached to dead, thatched grass. Microscopically, *Psilocybe strictipes* has smaller and narrower spores than *Psilocybe semilanceata*. The name *strictipes* refers to the tough or hardened texture of the stem, especially the base, in drying.
A variety *Psilocybe strictipes* abundantly in western Oregon in close association with highland bentgrass (*Agrostis tenuis*) where thousands of acres are dedicated to the commercial cultivation of grass seed - a major industry in that region. The prolific fruitings of *Psilocybe strictipes* in these grasslands and the subsequent distribution of spore-dusted seeds represents a huge launching platform of germ plasm to faraway lawns, golf courses, and institutions of higher learning. The potential distribution of this species through the commercial distribution of lawn seed is mind-boggling. *Psilocybe strictipes* is likely to be much more common than

presently realized.

Frequently found along trails or road-sides bordering deciduous forests. Fruiting April to July in temperate southern Japan and subtropical Indonesia. Probably extensively distributed between these two localities.

Comment: Moderately potent. Koike et al. (1981) detected psilocybin and psilocin. This squat, collyboid, and annulate *Psilocybe* is unique to Asia. Partial veil white, finely cortinate, soon disappearing and leaving fragile traces in the upper regions of the stem.

Microscopic feat.:

Basidio/Spores: Purplish brown in deposit, subellipsoid in both side and face view, 13-15 by 6.6-7.7 µm.
Basidia: 4-spored, infrequently 2-spored.
Pleurocistidia: 22-47 by 6-16.5 µm, fusoid-ventricose, mucronate with an elongated neck 2-4.5 µm. thick.
Cheilocystidia: Similar in form to pleurocystidia, 17-29 by 5.5-11 µm.

Habitat: Solitary to gregarious in complex habitats such as soils rich in woody debris, decaying piles of leaves and twigs, sandy woody soils, gardens, and amongst bark chips from pine (*Pinus radiata*). Found from May through August. Known only from Australia and Tasmania.

Comment: Moderately to potently active, judging by the bruising reaction. No analyses are known to me. This species is in the center of a constellation of close relatives, including *Psilocybe australiana*, *Psilocybe eucalypta*, and *Psilocybe tasmaniana*. A study by Chang and Mills (1992) sought to show synonymy between these taxa but, upon close reading of their work, some doubt remains if they had the true *Psilocybe subaeruginosa* and were making valid comparisons. *Psilocybe subaeruginosa* has pigmented pleurocystidia and is described as "chocolate brown", features Chang and Mills admit to not finding in any of the collections they studied. The chocolate brown cystidia of *Psilocybe subaeruginosa* differentiates this taxon from the mushrooms mentioned above, all of which have hyaline cystidia (Guzmán, Bandala, and King 1993). Hence, I think sufficient doubt is cast on their arguments for conspecificity. Better studies are needed.

Macroscopic feat.:

Cap/Pileus: 2-3 cm broad. Conic to campanulate expanding in age to convex to subumbonate. Surface smooth viscid when wet and striate near the margin. Ochraceous to yellowish brown, sometimes olive toned, hygrophanous from the disc, fading in drying to light straw colored, bruising dark bluish where injured.
Gills/Lamellae: Attachment adnate to sinuate, pale brownish to purplish brown to deep violet with concolorous edges.
Stem/Stipe: 40-70 mm long by 3-5 mm thick. Equal to slightly enlarging and often curved at the base, flexuous, hollow, and featuring a coating of whitish fibrils in the lower regions. Whitish at first, soon ochraceous or reddish brown, especially towards the base. Partial veil cortinate, fragile, and usually not leaving a fibrillose annular zone on the stem. Flesh bruising bluish where injured.

Microscopic feat.:

Basidio/Spores: Dark purplish brown in deposit, subellipsoid in side view; nearly ovoid in face view, 5.5-7.5 (8.5) by 3.3-4.4 (5.5) µm.
Basidia: 4-spored.
Pleurocistidia: Absent.
Cheilocystidia: 15-22 by 5-7.5 µm, fusoid ventricose with an abbreviated or elongated neck 1-1.5 µm thick.

Habitat: Gregarious to cespitose, fruiting from May to September in Japan (Otsu City, Shiga-Prefecture) in soils covered with mosses or grasses in open forests, often under pines, particularly *Pinus densiflora*.

Comment: Potency unknown, likely to be moderately to highly active. Microscopically nearly identical to *Psilocybe caerulipes*, but differing in the size of the spores and its ecological distribution. Furthermore, Guzmán (1983) notes that *Psilocybe caerulipes* may be conspecific with *Psilocybe muliercula* (=*Psilocybe wassonii*) as they are difficult to separate taxonomically. Interfertility studies would clear up the question of conspecificity. See also *Psilocybe venenata*.

Macroscopic feat.:

Cap/Pileus: 0.5-2 cm broad. Conic to campanulate, expanding with age to broadly campanulate but not sharply umbonate. Surface smooth, viscid when moist from a separable gelatinous pellicle, and translucent-striate near the margin. Ochraceous brown to olive brown, hygrophanous, fading in drying to a straw color. Flesh whitish, bruising bluish where injured.
Gills/Lamellae: Attachment adnexed, clay becoming violaceous brown, with whitish edges.
Stem/Stipe: 25-45 mm long 2-3 mm thick, equal to slightly enlarged towards the base, white to dingy white or pallid, bruising bluish where injured. Well-developed partial veil cortinate, usually leaving a fibrillose annular zone that can approach a true annulus in the upper regions of the stem. Flesh whitish, bruising bluish.

Microscopic feat.:

Basidio/Spores: Dark violaceous brown in deposit, subellipsoid in face view, and subellipsoid, sometimes irregularly so, in side view, 10-14 by 6.6-7.7 µm.
Basidia: 4-spored.
Pleurocistidia: Absent.
Cheilocystidia: 20-28 by 5-6.6 µm, fusoid-ventricose or more frequently lageniform with an extended neck 1-2 1-2 µm broad.

Habitat: Solitary to gregarious on dung, primarily in grassy areas. Reported from locations near Siltcoos Station, Oregon, and Vancouver, British Columbia in October through November, and near Chovetten, Chile, in August. Probably much more extensive in its distribution than presently realized. I have found this species in habitats also supporting *Psilocybe semilanceata* and *Psilocybe liniformans*.

Comment: Active, but I do not know how potent. This mushroom resembles *Psilocybe semilanceata* and is definitively separated from it by microscopic features. Macroscopically, this species is distinguished from *Psilocybe semilanceata* if the annulus of *Psilocybe subfimetaria* persists into maturity. Furthermore, *Psilocybe semilanceata* is sharply umbonate, while *Psilocybe subfimetaria* is not. *Psilocybe subfimetaria* is a relatively rare species and is very close microscopically to *Psilocybe fimetaria*, from which it is separated by spore size. Also, *Psilocybe subfimetaria* often grows directly out of dung, while *Psilocybe semilanceata* prefers grasses. (Manured grasslands can make this judgment difficult.) The overall aspect, fairly persistent annular zone, and nonpapillate cap can help narrow the field of candidates to *Psilocybe subfimetaria*. See also *Psilocybe stuntzii* var. *tenuis*.

Epicutis: Subgelatinized, formed by hyaline repent hyphae 2.4-4 µm wide.
Hypodermium: With subglobose elements mixed with hyphae 3-12 µm in diam, hyaline or incrusted with brown yellowish pigment. Clamp connections present.

Habitat: In small groups on soil, in open places of subtropical (mesophytic) forests. Known from Guatemala and Mexico.

Studied material: GUATEMALA: approx. 25km south of Guatemala City, Santa Elena Barillas, Jun. 28, 1990, Sommerkamp 371 (Herb. Univ. San Carlos Guatemala & XAL). MEXICO: State of Veracruz, old road Xalapa to Coatepec, km 2.5, Parque Ecológico F.J. Clavijero, Oct. 6, 1986, Montoya 910 (Holotype, XAL). Discussion: The subbulbous, hollow base of the stipe, the mycenoid habit, the branched cheilocystidia and narrow pleurocystidia are the most typical features of this caerulescent species. *Psilocybe herrerae* Guzmán, is a close taxon, but differs in the more branched cheilocystidia and thicker pleurocystidia (6-9 µm), and in the presence of pseudorhiza (Guzmán, 1983). Due to the form and size of the spores, this species belongs to Sect. Cordispora. *Psilocybe subtropicalis* is widely distributed in subtropical forests. *Psilocybe mexicana* grows also in the same Guatemaltecan locality.

Habitat: Usually found growing in grassy areas, in well-manured grounds or in dung. Also reported growing in mossy areas and in decayed conifer substrata. Grows in the late spring to summer, reported from the United States (Washington, Oregon, Michigan, New York) and Scotland (Shetland). Thought to be widely distributed.

Comment: Not active. Since this species can grow on such a wide spectrum of habitats, I would expect that its actual distribution is far more extensive than presently reported. Psilocybe tampanensis

Psilocybe tampanensis Guzmán & S.H.Pollock (1978)

A very interesting species. It has only been collected in the wild twice. All cultures that are in circulation today originate from one single specimen that was cloned by mycologist Stephen Pollock in 1977. This mushroom was found in Tampa, Florida hence the name tampanensis.
This species produces sclerotia (hardened mycelial structures) on grass seed and in the casing layer.
Variability within a multispore germination is great resulting in some strains that are good sclerotia-producers, some that are good fruitbody-producers, some that are both and some that are neither.
We recommend making different isolates from a multispore germination and testing each of them for their properties. Alternatively you can start with multispore cultures and clone some mushrooms or sclerotia.
Because of successive cloning for years most available strains are heavily degenerated and produce no or only sterile (sporeless) mushrooms.
We have been working for some time with a strain that did not produce fertile mushrooms but have recently acquired new one. This strain does produce fertile fruitbodies and although they are not perfectly shaped they do produce visible sporeprints.
We grow the sclerotia and fruitbodies of this species on sterilised grass seed (110 grams seed / 180 ml water). We have had jars that produced up to 70 grams (wet weight) of sclerotia in 4 months!

Substrate:
ryegrass seeds, cow manure.

colonization/fruiting: 24-27°C / 22-24°C

Cap/Pileus: 1-2 cm broad. Convex to subcampanulate, but not umbonate or papillate. Surface smooth, subviscid when moist, striate only near the margin, which is often adorned with whitish remnants from the veil. Tawny orangish brown, hygrophanous, fading in drying to a dull straw color or dingy yellow.
Gills/Lamellae: Attachment adnate, becoming purplish brown with spore maturity, with the edges remaining whitish.
Stem/Stipe: 40-65 mm long by 1-2 mm thick. Equal overall. Surface silky fibrillose, white to nearly concolorous with the cap. Flesh bruising bluish where injured, especially at the base. Partial veil well developed, finely cortinate, white, soon disappearing.

Microscopic feat.:

Basidio/Spores: Dark purplish brown in deposit, ellipsoid to subellipsoid in side view and subovoid in face view, 10-13 (15) by 7-8.8 µm.
Basidia: 4-spored.
Pleurocistidia: 19-24 by 5.5-9.9 µm, fusoid-ventricose with an abbreviated apex, 1.6-2.7 µm broad.
Cheilocystidia: Fusoid ventricose to sublageniform, with extended neck 5-11 by 1.6-3.3 µm.

Habitat: Grows solitary or gregariously in April and May on dung (possibly kangaroo) or in dung-enriched debris in open areas within *Eucalyptus* forests. Reported from Tasmania, New Zealand, and Australia.

Comment: Active, potency unknown. This species is closely related to *Psilocybe subaeruginosa* and *Psilocybe cyanescens*. Chang and Mills (1992) tried to make *Psilocybe tasmaniana*, *Psilocybe australiana* i *Psilocybe eucalypta* subordinate synonyms of *Psilocybe subaeruginosa*. For reasons described on pages 91-92, I am skeptical of their interpretations. Furthermore, they made conclusions about the identification of mushrooms that they called *Psilocybe tasmaniana* that are not referenced against any type listed by Guzmán and Watling, which is surprising considering the strong taxonomic proposals they put forward. If their identifications were in error, and they then "proved" synonymy between the collections, the analyzed collections may indeed be biologically compatible because they incorrectly delimited one species into the other aforementioned taxa. Interestingly, Johnston and Buchanan (1996), while endorsing most of the proposed synonymy of Chang and Mills, selectively exclude *Psilocybe tasmaniana* as a species found in New Zealand (nor do they list it as a synonym!) although Chang and Mills (1992) references a collection from Taranak, New Zealand. Clearly, more studies are needed, using better reference standards and systematics, to adequately answer the questions raised here.

Macroscopic feat.:

Cap/Pileus: 3-7 cm broad. Obtusely conic at first, soon becoming convex to broadly convex, and finally nearly plane with or without an umbo. Viscid when moist from a gelatinous pellicle that is usually separable, soon drying. Surface adorned with whitish, floccose scales, especially near the margin. Orangish red to reddish brown or brick red. Margin initially ornamented with small scales, soon becoming smooth.
Gills/Lamellae: Attachment adnate to adnexed, or sinuate, sometimes uncinate, close to subdistant, moderately broad, with two to three tiers of intermediate gills. Pallid gray at first, soon becoming grayish brown and eventually dark purplish brown when fully mature.
Stem/Stipe: 50-100 (120) mm long by 3.7 (8) mm thick. Nearly equal to swollen and often curved at the base. Hollow in age. Pallid towards the apex and more brownish below. Covered at first with small brown to reddish brown floccose scales to the annulus, and usually with orangish rhizomorphs protruding about the base. Partial veil membranous, fragile, leaving a superior membranous annulus often absent in age.

Microscopic feat.:

Basidio/Spores: Grayish purplish brown in deposit, close to *Psilocybe squamosa*, in size, but with an eccentric germ pore, 11-14 by 6.6-8.5 µm.
Basidia: 4-spored.
Pleurocistidia: Absent.
Cheilocystidia: (36) 44-66 by 3.3-6 µm, sublageniform to filamentous, submucronate, with an extended and flexuous neck, 3-4 µm.

Habitat: Scattered in the fall in decayed wood substratum or wood debris. Reported from the United States (the Pacific Northwest, New York, Maryland), Japan, and northern to central Europe. Probably more widely distributed across the world.

Comment: Not active, edible according to some, but not palatable. Høiland (1978) detected no psilocybin. This species was once considered a variety of *Stropharia squamosa* (now a *Psilocybe*) and is very similar to it in appearance, differing in the cap coloration.

Studied material: URUGUAY, Montevideo, Parque Nacional Carrasco, April 3, 1960, García Zorrón 2439 (Holotype BAFC: Isotypes in MICH and ENCB).

Discussion: The name *Psilocybe uruguayensis* was given to a collection in BAFC by Singer but remained unpublished. Singer thinks that this species stains blue when fresh. It is close to *Psilocybe blattariopsis* (Speg.) Sing. but this species has brown pleurocystidia according to a study of the type (Spegazzini 1535, LPS). It is also close to *Psilocybe subaeruginascens* Höhnel, *Psilocybe stuntzii* Guzmán & Ott and *Psilocybe venenata* (Imai) Imaz. & Hongo, but differs in the size of the cheilocystidia and spores; it is interesting to see the geographical distribution of these species; *Psilocybe subaeruginascens* is only known from Java, *Psilocybe venenata* from Japan and *Psilocybe stuntzii* from the NW of North America. (See discussion of *Psilocybe blattariopsis*).

Psilocybe uxpanapensis

Psilocybe uxpanapensis Guzmán (1979)

Macroscopic feat.:

Cap/Pileus: 19-30 mm in diam., conic to subconvex or subumbonate, sometimes becoming plane or depressed at the disc. Even and glabrous, marked with translucent striations when moist, lubricous or subviscid, hygrophanous. Color reddish-brown or chocolate-brown to pale ochre. Blackish when old and staining blue in young specimens when handled.
Gills/Lamellae: Adnate or adnexed to sinuate. Brownish-violet to blackish-violet with white floccose edges.
Stem/Stipe: 40-90 x 1.3 mm. Equal but sinuous and flexuous, hollow, reddish-brown or brownish, fading to blackish. Densely fibrillose floccose from whitish appressed fibrils. Turning Blue where cut or injured.

Microscopic feat.:

Basidio/Spores: (4.9-) 5.5-6.6 (-7.7) x 4.4-5.5 (-6) x 3.5-4.4 µ. Subrhomboid or rhomboid in the front and subellipsoid from the side, thick walled and with a distinct germ pore. Sporeprint yellow-brown.

Habitat: Solitary or gregarious on soil or near trails.

Distribution: In tropical virgin rain forests. Known only from Mexico (Uxpanapa region).

Season: During the summer rains.

Dosage: Unknown.

Comment: According to Guzmán, many fungi from the tropical virgin rainforests are almost lost. The vegetation for this and other similar species are almost destroyed throughout Mexico. The very area where this species was collected by Guzmán and Dr. A. L. Welden in 1976 was completely overturned in 1978 and is now a subagricultural land and meadow lands region. The name of this species is for the type locality.

Psilocybe venenata

synonyms:
Psilocybe venenata (Imai) Imazecki
Psilocybe fasciata Hongo

Macroscopic feat.:

Cap/Pileus: 1-6 cm broad. Initially conic, soon convex to subumbonate to nearly plane in age, often depressed in the center with slightly upturned margins. Chestnut to cinnamon brown to olive brown, then pinkish buff to light blonde brown in drying, often grayish green, rarely whitish, readily bruising bluish where injured. Surface smooth, viscid when moist, translucent-striate near the margin, which is often adorned with minute fibrillose veil remnants, especially when young.
Gills/Lamellae: Attachment adnate to adnexed, whitish at first, soon light grayish to dingy yellowish, and eventually purplish brown to grayish violet brown with spore maturity. Edges pallid to whitish fringed.
Stem/Stipe: 40-90 mm long by 2-6 (9) mm thick, equal to uneven, fibrous, silky white, enlarged near the base from thick white rhizomorphs radiate. Partial veil thickly cortinate to nearly floccose, leaving a fragile fibrillose annulus or annular zone in the superior regions of the stem, soon disappearing or dusted with purplish brown spores. Flesh whitish, bruising azure blue where bruised.

Microscopic feat.:

Basidio/Spores: Dark purplish brown in deposit, subellipsoid, (8) 9.9-12 (14) by 5.5-7 (8.8) µm.
Basidia: 4-spored.
Pleurocistidia: Absent.
Cheilocystidia: 17-30 (36) by 4.4-7.5 µm, fusoid-ventricose to lageniform with an extended and flexuous neck, 1-2.5 µm thick.

Habitat: Gregarious to cespitose in the summer and autumn in disturbed habitats, in soils rich with lignicolous debris, and in deciduous or bamboo forests. Also found in composting soils rich with mixtures of rice hulls, straw or manure. Sometimes grows in lawns, along roadsides, or along interfaces in Japanese gardens. Reported only from Japan, but I suspect that this species is probably more widely distributed.

Comment: Probably potent, although no analyses are known to me. *Psilocybe venenata* is a misnomer, as no deaths have actually occurred (despite erroneous reports) (Ott 1993). The symptoms produced are typical of other potent psilocybin species. For most collectors, the lighter color, strong bluing reaction, cespitose habit, and locality narrow the field of candidates to this species. Given its preference for habitats, this species is likely to be cultivated outdoors amongst bamboo or in gardenlike settings in a similar fashion to *Psilocybe cyanescens* and *Psilocybe azurescens*. See also *Psilocybe argentipes* and *Psilocybe subcaerulipes*.

synonyms:
Psilocybe villarrealii Guzmán

Macroscopic feat.:

Cap/Pileus: 40-50 mm long, convexed and plain, hygrophanous and ochraceus with some bluing and blue green along the edge of the cap. Margin translucent-striate.
Gills/Lamellae: Adnate to subsinuate, and somewhat violaceous in color at the margin of the gills.
Stem/Stipe: 50-60 x 4-7 mm. Reddish brown with white scabulous fibrils on stipe. Bruising blue when damaged or with age.

Microscopic feat.:

Basidio/Spores: (5.5-) 6.5-7.5 (-8) (-9) x (4.5) 5-6 µm. Sporeprint: Violet to Chocolate-brown.

Habitat: Common in the Mexican State of Jalisco, the influence of many new, as well as old ecosystems and microclimates are important for the distribution of these species. Riparian forests extend from sea level to about 2800 m elevation, with species of *Populus* predominating in arid and semi-arid regions of northern Mexico and species of *Alnus* in more temperate zones with cooler climates area good habitat for finding this species. *Psilocybe villarrealiae* is a big mushroom, preferring to grow near rivers and along river creeks with vegetation classified as clod. Subtropical forests appear to be a natural humid habitat for these species, as well as are open spaces and under bushes. Sometimes, large collections of this species can be observed near *Magnolia* spp., and *Alnus* spp., where wood debris is buried and mixed with muddy soil, red soil, in pine forest mixed with oaks, and in subtropical forests near small creeks.

Distribution: It has a logistic distribution in Jalisco and can be found in the towns of San Sebastian del Oeste, Mascota, and Zapopan. *Psilocybe villarrealiae* also occurs in many other regions of Jalisco such as in Sierra de Quila.

Season: Generally, rainy season occurs in certain parts of Mexico from June through September. However, we report that sometimes the mushrooms appear as early as May and continue to fruit until October.

Dosage: Unknown.

Comment: *Psilocybe villarrealiae* acts as a second decomposer, growing from sawdust, which we were able to observe in the town of Mascota, and we also found it to be growing out doors as well.

Psilocybe washingtonensis

Psilocybe washingtonensis A.H.Sm. (1946)

nonactive

Macroscopic feat.:

Cap/Pileus: 1-2 cm broad. Obtusely conic to convex. Margin incurved at first, then straight. Deep walnut brown, lighter towards the margin, hygrophanous, fading to dull cinnamon or pale pecan in drying. Surface smooth, though the margin may be ornamented with faint remnants of the veil, viscid when moist from a gelatinous pellicle, separable only in shreds when wet. Context thin, pliant, and nearly concolorous with the cap when moist.
Gills/Lamellae: Attachment adnate or subdecurrent, close to subdistant, with two or three tiers of intermediate gills. Color slightly darker than the cap at maturity.
Stem/Stipe: 30-50 mm long by 1.5-2.5 mm thick. Equal, tubular, and pliant. Concolorous with the cap, but becoming blackish brown in age from the base upwards. Surface covered with grayish fibrils and adorned with grayish mat of mycelium around the base. Flesh dark brown, fading in drying to pallid tan. Partial veil thinly cortinate, leaving fibrillose patches on the stem and remnants along the cap margin.

Microscopic feat.:

Basidio/Spores: Purplish brown in deposit, ellipsoid to slightly ovoid, 6-7.5 (8) by 4-4.5 µm.
Basidia: 4-spored.
Pleurocistidia: 38-56 (64) by 9-12 µm, narrowly fusoid-ventricose to lageniform with expanded necks.
Cheilocystidia: 18-38 by 7-12 µm, variable, fusoid-ventricose, often mucronate, or clavate to capitate with an abbreviated neck.

Habitat: Scattered to gregarious in forests, directly on decaying conifer wood in the fall. Reported from Mt. Angeles on the Olympic Peninsula of Washington State and along the Salmon River near Welches, Oregon. Probably more widely distributed.

Comment: Activity unknown. *Psilocybe washingtonensis* could be weakly psilocybin. It bears similarity to *Psilocybe physaloides* and to a lesser degree *Psilocybe pelliculosa*, although the latter species lacks pleurocystidia. The overall aspect of this mushroom places it into a cluster of difficult-to-delineate taxa, unless microscopic examination is conducted. Several mycenoid Hypholomas (=Naematolomas), look very similar, including *Hypholomas udum*, *Hypholomas dispersum*, and allies. See also *Psilocybe silvatica* and *Psilocybe crobula*.

Stem/Stipe: 30-40 mm long by 1-2 mm thick, equal to slightly enlarged, hollow, reddish brown to blackish brown, and covered with a sheath of white floccose fibrillose patches. Narrowing towards the base into a long pseudorhiza up to 10 mm long. Partial veil cortinate, fragile, and soon disappearing.

Basidia: 4-spored.
Pleurocistidia: Absent.
Cheilocystidia: 14-28 by 5-6.6 µm, ventricose near the base and sublageniform with a flexuous neck 1-2 µm thick, sometimes branched.

Habitat: Solitary or in small groups in open areas of subtropical deciduous forests. Originally found from Veracruz, Mexico, in June and July, at an elevation of 1700-1800 meters. Probably more widely distributed.

Comment: Active, but potency unknown. Originally found by the late Steven Pollock, and re-collected by Jim Jacobs, this relatively rare species is distinct for its solitary habit and long pseudorhiza. Named to honor the works of the Wassons, this species is not related to *Psilocybe wassonii* (=*Psilocybe muliercula*). See also *Psilocybe herrerae*, a similar species with a long pseudorhiza.

Studied material: India, Kerala State, Wayanad District, Muthanga, 21 July 1999, *Thomas T-320a* (holotype, XAL; isotype, L); 25 July 1999, *Thomas T-320b* (XAL, L); 27 July 1999, *Thomas T-320c* (XAL, L); 31 October 1999, *Thomas T-320d* (XAL, L).

Discussion: The annulus, the subrhomboid, thick-walled spores, and the bluing reaction place this new species in Sect. *Stuntzii* Guzmán (Guzmán, 1983). Psilocybe weilii

Psilocybe weilii Guzmán, Stamets & F. Tapia

Macroscopic feat.:

Cap/Pileus: 2-6 cm broad. Campanulate to bluntly conic with an inrolled margin when young, then incurved, often with an irregular, soon expanding to broadly convex to nearly plane, to uplifted in age. Dark chestnut brown to deep olivaceous brown, typically with a blackish brown zone around the disc, where flesh is 3-4 mm thick at its center. Strongly hygrophanous, fading in drying to pallid brown to light brown. Flesh whitish, bruising bluish. Surface viscid when moist from a separable gelatinous pellicle, translucent-straite near the margin, which can split in age and become tough and opaque in drying.
Gills/Lamellae: Attachment adnate to sinuate with two tiers of intermediate gills, close, even, broad, light brown overall with pallid, floccose edges. Becoming dark chocolate brown at maturity.
Stem/Stipe: 25-70 mm long by 4-8 mm thick. Equal, swelling towards the base, which projects white rhizomorphs. White, becoming dingy brown, bruising bluish overall in age or from drying, covered with a well-developed sheath of whitish fibrillose patches below, and pruinose above. Cartilaginous, strigose, hollow, stuffed with a whitish pith. Partial veil cortinate, leaving a fibrillose annular zone sometimes dusted with purplish violet-brown spores.

Microscopic feat.:

Basidio/Spores: Dark violet grayish black in deposit, subellipsoid in side view, subrhomboid to subellipsoid in face view, 5.5-6.5 by 4-5 µm in side view.
Basidia: 4-spored.
Pleurocistidia: Abundant, subfusoid or ventricose-rostrate with short apex, or sublageniform, 10.5-21.5 (24) by 5-9.5 (10.5) µm.
Cheilocystidia: Lageniform with short, single, or branched neck, 20-37.5 by 5-6.5 µm.

Habitat: Gregarious to cespitose, sometimes scattered in red clay soil topped with a thin layer of needles from loblolly pine (*Pinus taeda*) underneath sweetgum (*Liquidambar styraciflua*). First reported from southeastern Cherokee County, in northern Georgia, after hurricane Opal swept through in 1995. Fruiting from early September through November, between temperatures of 45°-80°F, preferring 60°C-75°.

Comment: 0.61% psilocybin, 0.27% psilocin, 0.05% baeocystin, and 0.32% tryptophan. This is the first report of a lignicolous, caerulescent *Psilocybe* from Georgia. The association with pine needles, along an interface ecosystem (just beyond the edge of an eight-year-old yard lined with shrubs, and in red-clay soils), are habits typical of many other Psilocybes. Additionally, the strong bluing reaction and its tendency to form clusters are characteristics also shared with *Psilocybe caerulescens*, *Psilocybe baeocystis*, *Psilocybe aztecorum* and *Psilocybe heliconia*. The name *Psilocybe weilii* is being reserved as a provisional name (nom. prov.) until the name is published in a mycological journal. (Guzmán, Tapia, and Stamets 1996). The name honors Andrew Weil and his role in promoting the beneficial properties of mushrooms.

Psilocybe weraroa

Psilocybe weraroa Borov., Oborník & Noordel. (2011)

synonyms:
Secotium novae-zelandiae G.Cunn. (1924)
Weraroa novae-zelandiae (G.Cunn.) Singer (1958)

Macroscopic feat.:

Cap/Pileus: 10-30 mm in diameter, 30-50 mm tall. Light brown to tan when very young, maturing to bluish grey often with blue to bluish green stains especially where damaged.
Stem/Stipe: Up to 40 mm long, cartilaginous, white to grayish blue, yellowish brown at the base, bluing where damaged.
Gills/Lamellae: Chambered, chocolate brown gleba.

Microscopic feat.:

Basidio/Spores: 12-14 (17) by (6) 7-8.5 (10.8) µm, elliptical and smooth, brown. Spores are not discharged as prints and must be extracted by centrifuge to concentrate samples for microscopy.

Habitat: Dead tree ferns and other woody debris. Climate temperate.

Comment: *Weraroa novae-zelandiae* (*Weraroa novaezelandiae*) is a rare secotioid form of caerulescent *Psilocybe* known only from the North Island of New Zealand. In general, secotioid mushrooms appear to be lumpy, malformed mushrooms that never open up to expose their gills (or tubes in boletes). A cross section will reveal a convoluted mass of gills and sometimes a stem. Since the cap never opens up, the spores are not forcibly discharged and the mushroom must rely on animals or insects to eat and disperse them. Slugs seem to be especially attracted to *Weraroa novae-zelandiae* and most specimens are found to have slug damage. If not eaten, the mushrooms can persist for months before slowly succumbing to decay. *Weraroa novae-zelandiae* was first described in detail by Cunningham in 1924 (as *Secotium novae-zelandiae*). In 1958, Singer made the connection between *Weraroa novae-zelandiae* and the bluing Psilocybes based on similar spore types and blue staining. He further speculated that Weraroa was the probable ancestor of the Strophariaceae (the family containing the genera *Hypholoma*, *Psilocybe* and *Stropharia*). Singer didn't mention any hallucinogenic properties and no one will for almost 50 more years.
In 2005 Internet postings about the recreational use of *Weraroa novae-zelandiae* for its hallucinogenic effects were noticed by New Zealand mycologist Peter Johnston. The postings prompted molecular work (currently unpublished) by secotioid expert Ross Beever which reveals that *Weraroa novae-zelandiae* is very closely related to *Psilocybe subaeruginosa*, which appears to be synonymous with *Psilocybe cyanescens*. Cultivation experiments also support this close affinity with *Psilocybe cyanescens* and other temperate wood-inhabiting Psilocybes. *Weraroa novae-zelandiae* now appears to be only distantly related to other species of Weraroa such as *Weraroa erythrocephala* and *Weraroa virescens*.

Cap/Pileus: 25-65 mm diam., subconvex to subumbonate, smooth to substriate at the margin, some rimose in old specimens, viscid to subviscid, hygrophanous, brown or reddish brown to brownish yellow, some straw-colored.
Gills/Lamellae: Subadnate or sinuate, yellowish violaceous to brownish violaceous or chocolate brown, somewhat mottled; edges whitish to concolorous.
Stem/Stipe: 80-95 x 5-9 mm, cylindrical, equal or slightly subbulbous, hollow, whitish to yellowish, finally brown reddish to blackish; staining blue when touched or injured; covered by floccose white fibrils toward the base.
Context: White and fleshy in the pileus, yellowish and subgelatinous to subcartilaginous in the stipe; staining blue when cut.
Odor: Farinaceous.

Microscopic feat.:

Basidio/Spores: (6-) 6.6-7.7 (-8.5) x 5.5-6.6 (-7.1) x 3.5-5.5 µm, subrhomboid, some obscurely angular in face view, but broadly elliptic or subelliptic in side view, smooth, yellowish brown thick walled, with broad flattened germ pore.
Basidia: 20-30 x 6-8 µm, four spored, vesiculose-pyriform, with a slight constriction in the middle.
Pleurocistidia: 15-22 x 5.-6.6 µm, hyaline, not abundant, vesiculose-fusoid, attenuate above and with a rounded nucro or sublageniform, neck 3.3-4 µm across.
Cheilocystidia: 13-22 x 4.5-6 µm, hyaline, ventricose-rostrate, with necks 2-2.5 µm, forming a sterile band along the gill edge.
Subhymenium: Yellowish with irregular brownish yellow pigment incrustations.
Trama: Hyaline to yellowish, parallel, colored by brownish yellow pigmented irregularly incrusted hyphae which often resemble collapsed chrysocystidia.
Epicutis: Formed by subgelatinized parallel hyphae, which are elongated to subglobose, hyaline to brownish.
Hypodermium: Yellowish or hyaline, with some latiferous hyphae, hyaline or brownish, 5-7 µm broad. Clamp connections present.

Habitat: Gregarious on grassy soil outside of the subtropical forest at 900 m elevation.

Studied material: ARGENTINA, road Tucumán to Tafi del Valle, 3 km W of Station Aforos, Febr. 18, 1971, Guzmán 8683 (holotype BAFC; isotype ENCB).

Discussion: *Psilocybe wrightii* is close to *Psilocybe caerulescens* Murr. but the pleurocystidia and the pigmented trama separate it from the latter as well as the thin floccose stipe. The report of *Psilocybe caerulescens* by Singer and Digilio (1951) from the Rio de los Sosas, which is close to Aforo Station, it is possible a record of *Psilocybe wrightii* (no material of that species was available to the author in LIL and in BAFC). The species here described, is certainly hallucinogenic because of its bluing, and its taste and flavor. It is named after Dr. J.E. Wright, who helped the author during his collecting trip to Argentina in 1971.

Psilocybe subyungensis Guzmán (1978)

Macroscopic feat.:

Cap/Pileus: (0.5) 1-2 (2.5) cm, conic to campanulate at maturity, often adorned with a sharp umbo. Surface smooth, viscid, and translucent-striate most of the way to the disc when moist, pellicle not separable. Rusty brown to orangish brown to dark reddish brown, hygrophanous, fading in drying to dull yellowish brown or dingy straw colored. Bruising bluish where injured, and then blackish in drying.
Gills/Lamellae: Attachment adnate to adnexed, close to crowded, dull gray at first, soon purplish brown with spore maturity. Edges pale to nearly concolorous with gill surface.
Stem/Stipe: (25) 30-50 (60) mm long by 1.5-2.5 (3) mm thick, equal to enlarging towards the base. Surface covered with a sheath of dense whitish fibrils, pale brownish above and reddish brown to reddish brown-black near the base. Flesh bruising bluish, hollow, and fairly brittle. Partial veil cortinate, soon disappearing with maturity, leaving whitish fibrils along the cap margin and scant remnants on the upper regions of the stem.

Microscopic feat.:

Basidio/Spores: Dark purplish brown in deposit, rhomboid to subrhomboid to subellipsoid, (4.4) 5-6 (7) by 4-6 µm.
Basidia: 4-spored.
Pleurocistidia: 14-25 by 4.4-10.5 µm, ventricose below and mucronate at the apex.
Cheilocystidia: 14-33 by 4.4-7.7 µm, variable, ventricose to clavate to strangulated.

Habitat: Most frequently found in clusters or gregariously on rotting wood, sometimes at the bases of stumps, in coffee plantations or subtropical forests at 1000-2000 meters. Reported from Colombia and Ecuador, and extending north to Mexico. In June and July. Also reported from Bolivia in January. Probably more widely distributed than presently known.

Comment: Moderately active; analyses not available. This mushroom is distinct for its penchant for growing in great numbers on decomposing stumps or wood debris, its orangish color, and that the caps remain conic at maturity. I find the common name especially revealing. Few species resemble *Psilocybe yungensis*. See also *Psilocybe aztecorum*.

Studied material: PUERTO RICO, Mun. Río Grande, Luquillo Mountains, La Mina Recreation Area, Caimitillo Trail, 11 Jun 1997, coll. *Baroni*, ledger Nieves-Rivera PR-797 (PR-4401, NY); 23 May 2000, *Cantrell & Salgado* (holotype PR-6167, CFMR, isotype, XAL); Baño de Oro Trail, 7 Oct 2000, *Lodge & Pérez* (PR-6269, UPRRP, CFMR and XAL).

Discussion: *Psilocybe zapotecoantillarum* belong to section *Zapotecorum* because of the caerulescent nature of fresh basidiomata and thin-walled subellipsoid spores. *Psilocybe zapotecorum* Heim emend Guzmán (Guzmán 1983) differs most noticeably from *Psilocybe zapotecoantillarum* because of differences in the size and form of the pleurocystidia, which are longer and broader (20-38 x 5.5-14 µm) and of different morphologies (ventricose, fusoid-clavate, submucronate or pyriform). The form of the cheilocystidia in *Psilocybe zapotecorum* is also quite different (ventricose, fusoid-pyriform, ventricose-rostrate or lageniform) (Guzmán 1983).
Other taxa that should be compared with *Psilocybe zapotecoantillarum* are *Psilocybe angustipleurocystidiata* Guzmán and *Psilocybe sanctorum* Guzmán. These species differ from *Psilocybe zapotecoantillarum* in the size of the cheilocystidia, (10-) 13-24 x (2.5-) 5-6.5 (-8) µm and 13.5-29 x 6-17 µm, respectively. *Psilocybe subzapotecorum* Guzmán has two types of pleurocystidia (Guzmán 2000) and *Psilocybe barrerae* Cifuentes & Guzmán emend Guzmán has broader pleurocystidia, (6-) 7-10 (-12) µm (Guzmán et al 1999, Guzmán 2000). *Psilocybe halioconiae* Guzmán, Saldarriaga, Pineda, García & Velázquez from Colombia (Guzmán et al 1994) differs in the cheilocystidia, which are only up to 24 µm long and rarely sublageniform, ventricose-fusoid to submoniliform.

Stem/Stipe: 15-65 x 1.5-7 mm, equal to flared or tapered at base, Clay, light brown or dull Raw Umber, covered by whitish floccose scales, sooth or fibrillose, staining blue when handled, in dry specimens becoming reddish-brown, with blackish or dark reddish-brown spots.
Odor: Of radish. Taste fungoid.

Microscopic feat.:

Basidio/Spores: (5-) 5.5-6.5 (-7) x 3.5-4 x 3-3.5 µm (Q = 1.60), subellipsoid, both in face and side view, thin-walled, yellowish-brown, with a narrow germ pore.
Basidia: (13-) 14.5-17.5 x 5-5.5 µm, 4-sterigmate, hyaline, ventricose, with a median constriction.
Pleurocistidia: (11-) 12-16 (-17.5) x (3.5-) 4-5.5 µm, uncommon, hyaline, subventricose or subfusoid, with a short or long narrow neck.
Cheilocystidia: (12-) 14-36 (-40) x (4-) 5-7.5 (-9) µm, hyaline, subventricose or sublageniform, with an acute apex or a short or long neck, frequently irregularly branched, or some irregularly globose.
Subhymenium: Subcellular, with elements 2.5-7 µm wide, thin-walled, with encrusting pale brownish pigment.

Hypodermium: With subglobose, hyaline elements 2.5-18 (-20) µm, diam. thin-walled, with a pale brown encrusting pigment. Context with cylindric to inflated elements 2-20 µm wide hyaline to pale yellowish. Clamp connections common.

Habitat: MARTINIQUE, Lorrain River, 100 m altitude, 1 Jun 1975, *Fiard 318* (holotype K(M) 84366, as *Psilocybe yungensis* by Pegler).

Discussion: *Psilocybe zapotecocaribaea* belongs to section *Zapotecorum* because of the subellipsoid, thin-walled spores and bluing stipe tissues of the basidiomata. This collection originally was studied and considered by Peglera (1983) as *Psilocybe yungensis* Singer & A.H. Smith. However *Psilocybe yungensis* has distinctly rhomboid or subrhomboid, thick-walled basidiospores and belongs in section *Cordisporae*.
Psilocybe zapotecocaribea is somewhat similar to *Psilocybe zapotecoantillarum* but differs by the cheilocystidia that are not branched and rarely lageniform in *Psilocybe zapotecoantillarum*. *Psilocybe zapotecocaribaea* also has white floccose scales covering the stipe, which are lacking in *Psilocybe zapotecoantillarum*.
Psilocybe zapotecocaribaea also should be compared to *Psilocybe ramulosum* (Guzmán & Gononi) Guzmán. *Psilocybe ramulosum* differs from *Psilocybe zapotecocaribaea* in highly branched cheilocystidia and pleurocystidia that are longer than found in *Psilocybe zapotecaribaea* (15-35 (-45) µm long; Guzmán 1995).

Macroscopic feat.:

Cap/Pileus: 1-3 by 7 (11) cm, highly variable in form, conic to convex to subumbonate, and sometimes papillate and convoluted in age. Surface smooth, translucent-striate near the margin when moist. Reddish brown to organic brown, hygrophanous, fading to beige, orangish rose to straw in drying, quickly bruising blue to green to blackish where injured or in age.
Gills/Lamellae: Attachment sinuate or adnate, pale brown to violet brown to violet purple, with edges concolorous with gill face, or slightly paler.
Stem/Stipe: (40) 100-200 mm long by (3) 5-10 (12) mm thick, equal to slightly expanded at the base, sometimes with a pseudorhiza, at times flexuous or irregular in thickness. White to grayish to variably reddish brown or vinaceous, bluing when touched or injured, with blackish violet tones. Surface floccose above and strongly scabrous-strigose near the base.

Microscopic feat.:

Basidio/Spores: Purplish in deposit, violet brown in deposit, oblong-ellipsoid, (5.5) 6.6-7 (8.8) by 3.8-4.4 (5.5) µm.
Basidia: 4-spored.
Pleurocistidia: 20-38 by 5.5-14 µm, variable in form, fusoid-clavate, ventricose to submucronate, sometimes with irregularly divided apices.
Cheilocystidia: 13-27 by 3.5-6 µm, ventricose to fusoid, pyriform to lageniform, with an extended neck 1.5-2.2 µm.

Habitat: Cespitose to gregarious, rarely scattered, in swampy or muddy soils, in humus rich with leaves and wood debrs, in marshy deciduous forests, and in coffee plantations. Frequently found on the faces of ravines with exposed soils. Found in southern Mexico (600-1800 meters) and subtropical South America. (Collected in Colombia, Peru, Brazil, and Argentina.) Guzmán (1983) reported that this mushroom is sometimes found inside the mud houses of native peoples (Zapotecs), a curious if not spiritually prophetic phenomenon.

Comment: A potent and strongly bluing mushroom *Psilocybe zapotecorum* is comparatively large and can sometimes be covered with sand as it forces its way up through soils. From Brazilian specimens, Stijve and de Meijer (1993) found up to 0.30% psilocybin and 1% psilocin, which probably accounts for the strong bluing reaction. Not surprisingly, Heim and Hofmann (1958) found only 0.05% psilocybin and no psilocin in two-year-old specimens. One of the most curious species in the genus *Psilocybe*, this mushroom has a typically asymmetrical cap that is often convoluted in form. This mushroom is held in high esteem by native Mazatecs and Zapotecs. These two species have been confused frequently. The photographs labeled as *Psilocybe caerulescens* by Ott and Bigwood (1978) and as *Psilocybe caerulescens*-zapotecorum complex by Stamets (1978) are, in fact, *Psilocybe zapotecorum*. Heim and Callieux (1959) successfully fruited this species in Erlenmeyer flasks in sterilized, mixed compost after forty days of incubation (24-26°C).

synonyms:

Macroscopic feat.:

Cap/Pileus: Up to 25 mm wide. Hemispherical when young, then convex or rounded-humped. Gray brown. Strongly hygrophanous, drying pale, often with olive tone against the grooved edge. Apex wrinkled. Flesh whitish to pale gray-brown, with blue-green staining (type-study).
Gills/Lamellae: Attached, gray to pale brown, with a distinct olive tone, pied, mottled, and with a white/sterile gill edge.
Stem/Stipe: Stipe approximately 85 x 3 mm, slender, cylindrical, whitish/pale gray brown, staining blue-green when injured, base white-tomentose, dry, pruinose at the top, fibrillose toward base, hollow, brittle/fragile.

Microscopic feat.:

Basidio/Spores: 9-11.5 (13) x 7-8.5 x 5-5.5, smooth, opaque, clearly prolate, flattened in face-view, always longer than wide, germ pore even/flush.
Basidia: Basidia mostly 4-spored, rarely 2-spored. Approximately 20-25 x 8-10 µm. Sulphidia absent.
Pleurocistidia: Metuloids with yellow brown cell walls. Similar to the cyanescens-type, approximately 40-60 x 13 - 20 around, frequently apically encrusted with crystals.
Cheilocystidia: Cheilocystidia ventricose to bottle-shaped, tip often capitate-subcapitate, hyaline, approx 20-35 µm long.

Habitat: On soil between leaf litter. Occasionally rotten wood.

Studied material: Holotype from New Guinea, Papua, Bulolo, (Agathis Res, Horak, 2.2.1972, p.p.maj. Copelandia affinis (ZT 72/121)). As yet, this species is known only from New Guinea (Asia). Only two collections were examined (the type and one other) as part of Gerhardt's Type Study.

Discussion: This species is distinguished from *Panaeolus cyanescens* mainly by the smaller spores. It should also be mentioned that the soil or decomposing wood substrates would make this *Panaeolus* very unique. *Panaeolus lentisporus*, is very similar, but its spores are even more flattened, also has even broader spores with an extremely prominent protruding germ pore.

Comment: The type material collected was abundant and in good condition. In Gerhardt's research he found that a few specimens differed significantly in its spore for. He separated these into a collection that he labeled as No. 72/121-a, distinguished from the remaining material. From No. 72/121-a, he described *Panaeolus lentisporus*. The majority of the collection was in agreement with the characteristics given in the original description. Horak's dimensions for the spores were 9-10 x 7.5-9 x 5-6.5 µm (which is shorter). This may be because Horak had not measured spores that were produced from 2-spored basidia. Also, two-sterigmate basidia were not mentioned in Horak's description.

Panaeolus subbalteatus (Berk. & Broome) Sacc.

Panaeolus cinctulus is probably the most important psychoactive species in the genus *Panaeolus* in Europe. It grows directly on top of dung and on pastures that have been heavily fertilised. It can also be found on trash heaps or on compost or straw on which mushrooms are commercially cultivated.

We have grown this species on a mixture of dung and straw. We were also able to cultivate this species on sterilised grass seed cased with a mixture of peat and vermiculite (the same substrate that is used for *Psilocybe tampanensis* and *Psilocybe mexicana*). Although the fruitbodies were smaller than those grown on dung the first flush on grass seed was much bigger.

The first picture shows the first flush on cased sterilised grass seed. The second image shows some mushrooms grown on a sterilised mixture of straw and dung. The difference in appearance is very obvious although the same strain was used for inoculation.
The mycelium of this species had a characteristic flaky appearance, especially on grain and agar (third and fourth picture). It does not hold the substrate together firmly like for instance *Psilocybe cubensis*. The mycelium also forms small sclerotia-like structures.

Agaricus cyanescens
Copelandia anomala
Copelandia cyanescens

Copelandia westii

Were sure you've all heard about how potent *Panaeolus cyanescens* and *Panaeolus tropicalis* are. According to scientific reports published by P. Stamets and others, they are reported as the 4th most potent mushrooms God has put on this planet we call earth.

Panaeolus cyanescens grows scattered to gregariously in dung and fertilised pastures and fields. Widespread in most semitropical zones and occasionally seen in the Mediterranean region.

We have grown this species on a mixture of straw and dung with a thin casing layer. It is very important that the casing layer is not too thick as this species seems to have difficulty growing through it. A thin casing layer owever seems necessary for fruiting. This species is a very strong producer of psilocybin/psilocyn and mushrooms show a very strong blueing reaction when bruised.

Well, straight up, they are very potent and deliver an extremely beautiful vibe beyond description. So peacefull and colorfull, very potent yet about the "*smoothest*" mushroom experience out there in my opinion. Its hard to put it into words, you just have to experience them, and you will know. Pure bliss!

That is the good news. The bad news is they are not near as easy to grow as cubensis, but they do domesticate, and can be grown indoors with a little patience and lots of TLC. Plan on a few failures along with your success, its par for the course with this species as the mycelium is rather weak and easily contaminates. Ok, now that we just scared you off, come back. They are not that hard, we just suggest you don't try these until you've had experience growing other mushrooms. These are geared towards the intermediate and advanced growers.

Panaeolus fimicola

Panaeolus fimicola (Pers.) Gillet

synonyms:
Panaeolus ater (Lange) Kuhner & Romagnesi

Macroscopic feat.:

Cap/Pileus: 1-2(3) cm broad. Convex to campanulate, expanding to plane only during prolonged wet periods and in extreme age. Dingy gray to black, often with slight reddish hues, becoming paler in drying, leaving a darker grayish brown encircling zone along the margin. Margin striate when moist, not appendiculate, but sometimes irregular and uplifted at maturity Surface smooth, soon dry. Flesh moderately thick.
Gills/Lamellae: Attachment adnate to adnexed, broad, grayish, mottled, with grayish edges. Two to three tiers of intermediate gills present.
Stem/Stipe: 60-100 mm long by 1-2 mm thick. Equal, hollow, soft, and fragile. Dingy pale to whitish, especially towards the apex. Surface powdered above and striate below.

Microscopic feat.:

Basidio/Spores: Black in deposit, 11-14 by 7-9,5 µm, lemon shaped with an apical germ pore.
Basidia: 4-spored.
Pleurocistidia: Absent or only near to the gill edge and then similar in form to cheilocystidia.
Cheilocystidia: 25-35 (40) by 6-12 µm, mostly fusoid-ventricose.

Habitat: Growing scattered in soil or dung from the late spring and in the fall. Sometimes found in well-fertilized lawns and/or grassy places in woods. Widespread, reported from the Americas, Africa, and Europe.

Comment: Looking very much like a *Psilocybe*, especially in side view, this species is a latent producer of psilocybin, meaning that some collections, upon analysis, reveal a small amount of active indoles while other collections are devoid of them. Although widespread, this species is infrequently encountered compared to many other *Panaeoli*. Gerhardt (1996) showed synonymy between *Panaeolus fimicola* and *Panaeolus ater*. See also *Panaeolus castaneifolius*, *Panaeolus foenisecii*, and *Panaeolus papilionaceus*.

Cap/Pileus: The appearance of this species should match fairly closely with *Panaeolus affinis* (see description). Even Horak (briefl. release) apparently failed to noticed any differences in the collection of these mushrooms.
Gills/Lamellae: Similar to *Panaeolus affinis*.
Stem/Stipe: Similar to *Panaeolus affinis*.

Microscopic feat.:

Basidio/Spores: Approximately 8.5-10 (12) x 7-9 x 4.5-5. Smooth, opaque, extremely flattened. In face view they are often as long as wide! Germ pore brought forward.
Basidia: Basidia 4-spored (always?), About 18-22 x 8.5-10. Sulphidia absent.
Cheilocystidia: Ventricose, bottle-shaped, hyaline. Approximately 25-35 microns long.
Pleurocistidia: Metuloids of the cyanescens type. Approximately 40-63 z 11-19. Tip often decorated with crystals.

Habitat: Habitat (according Horak 1980) on soil between scattered, occasionally on rotten wood. The habitat and wide spores separate *Panaeolus lentisporus* from *Panaeolus affinis*.

Comment: *Panaeolus lentisporus* is distinguished from *Panaeolus affinis* by its more strongly flattened spores, which are often wider than they are long in face view. This character is unique in the genus. In direct comparison, they are clearly separable from *Panaeolus affinis* spores, which are always slightly longer than broad. The clearly brought-forward germ pore of the spores of *Panaeolus lentisporus* is another prominent feature. Microscopically, the spores also appear slightly darker, slightly flatter than in *Panaeolus affinis* and metuloids in its entirety. I am convinced that even more macroscopic or ecological differences would be discovered with more knowledge of the species.

Distribution: Holotype from New Guinea, Papua, Bulolo, Agathis Res, Horak, 02.02.1972, ppmin. "Copelandia affinis" (ZT 72/121a). So far known only from New Guinea (Asia).

Notes: Horak (briefl. release) kept all his material for a type. Furthermore, he was of the opinion that the different spore form comes about through probably immature fruiting bodies. Gerhardt disagreed because it is well known that for all species of the genus *Panaeolus*, the spores in the same lamella mature unequally (mottled gills). So every gill should always have both mature and immature spores, which can be seen from the different spore wall color. This would also mean that both spore forms would have to have been found within a specimen, but just the opposite was found: Gerhardt found with each fruitbody, either only one or the other spore type. Thus, wider spores represented a reliable character for the separation of the two species.

Pleurocistidia: Rare or absent, not projecting beyond plane of basidia.

Habitat: Grows scattered to gregariously

Distribution: Well kept grass, in lawns, parks and around well manicured buildings. Comment: Latently psilocybin, according to Ola'h (1969), and when so, weak. Some but not all collections of this species contain psilocybin. Distinguished from *Panaeolus foenisecii* by the color of the mature gills and spore deposit, which are very dark purplish gray-black.

Notes: It is easily mistaken for *Panaeolus cinctulus* and can be distinguished from that species by its more campanulate cap shape when young and slightly roughened spores.

Panaeolus tropicalis

Panaeolus tropicalis Ola'h

synonyms:
Copelandia tropicalis (Ola'h) Singer & R.A. Weeks

It grows in the wild on very old dung in tall grass and on the dung of wild animals in the tropics. A very (maybe the most) potent species of psilocybin mushroom on earth! This species is reported from Hawaii, Central Africa and Cambodia.
This mushroom is a close relative of *Panaeolus cyanescens* and can be grown in the same manner
Were very excited to bring you the very rare *Panaeolis tropicalis*. It is believed The *Panaeolus tropicalis* originated from the Hawaiian Islands and was carried over to S. Fork Florida on Pineapple ships years ago and became a native to certain areas of Florida.
Those that are fortunate enough to find or legally grow this very potent treasured species of *Panaeolus* are certainly blessed.
We have found the best way to grow this species is to take colonized rice and vermiculite or birdseed and vermiculite... and use the colonized grain to inoculate old dung.. preferably straw fed dung..and the then give it a light casing layer....It will also fruit on compost very well... and on straw.. but best results so far have been found with the old pasteurized dung.
I have to say... I'm very excited about this species as it is one of the most potent species I've ever tried.... as potent as the azure in my opinion.
According to all of our friends who have tried them in Amsterdam Its extremely visual... a very nice clean, vibe.....tasty...and just delivers a very powerful, colorful journey into the mind. We ask those of you who fruit this species to keep us updated on your progress so we can all share our experiments and make such a beautiful and potent species easier to fruit for beginners. At this point I would say this species is not for beginners at all.. but more geared towards the intermediate experimental and advanced growing level. Don't get us wrong it can be fruited.. but will be fruited much easier by those that have some good experience with growing mushrooms from straw.. dung.. and/or compost..... it will not fruit like your typical cubensis or from mmgg/pf style cakes... it will colonize this way.. but not fruit.. you will need your substrate as spawn to inoculate the above suggested substrates. All I have to say is.. this mushroom ROCKS..... the mind and spirit.. ..Open your mind.. because this mushroom is the KIND !!!.

Growth parameters:

Substrate:
Dung, straw, compost.
Temperature:
colonisation/fruiting: 26-29°C / 23-26°C

Panaeolus venezolanus

Panaeolus venezolanus Guzmán

synonyms:
Panaeolus annulatus Natarajan & Raman

Macroscopic feat.:

Cap/Pileus: 20-35 mm in diam, subcampanulate to campanulate, smooth to irregularly rimose, dry, brownish gray to ashy gray.
Gills/Lamellae: Sinuate, blackish-gray but mottled.
Stem/Stipe: 45-50 x 2-3 mm, cylindric but subbulbous, hollow, brownish gray to reddish, pruinose toward the base. Annulus membranaceous, thin, whitish to blackish from spores deposited.
Context: Thin, grayish at pileus, brownish at stipe, with taste and odor slightly farinaceous.

Microscopic feat.:

Basidio/Spores: (11-) 12-14.8 x 8.8-9.9 x 7.7-8.5 µm, limoniform to subovate, with broad germ pore and thick wall, brownish to dark brown or blackish (KOH).
Basidia: 21.7-30 x 9-11.2 µm, two- or fourspored, subcylindric or subpyriform, hyaline.
Pleurocistidia: None
Cheilocystidia: 24.7-34.5 x 6-9 µm, hyaline, subcylindric or vesiculose-elongated, abundant.
Subhymenium: And trama hyaline.
Epicutis: Dry, formed by brownish (KOH) vesiculose-cylindric elements emerging from the surface
Hypodermium: Hyaline. Clamp connections present but scarce.

Habitat: Gregarious on cow dung or on rich soils, in meadows of the subtropical forests. Known from Venezuela and possibly also present in subtropical and tropical regions of Mexico.

Studied material: VENEZUELA, N of Mérida, San Javier del Valle, July 27, 1971, Guzmán 9177 (Type, MER; isotype, ENCB)

Discussion: The well developed annulus in the adult fruiting bodies is a good feature to separate this species from all others known in the genus. It is rather close to *Panaeolus sphinctrinus* (Fr.) Quél., but the rimose pileus, the size of the spores, and the presence of an annulus separate it from that species. *Panaeolus sphinctrinus* does not have a ring, and the pileus is smooth. Its spores according to Singer (1960) are 12.5-14.5 x 8-10 µm; according to Ola'h (1969) are 14.5-18 x 10.5-12.6 µm, and according to Kühner & Romagnesi (1953) are 14-18 x 10-12 µm. Guzmán and Pérez Patraca (1972) reported two groups of *Panaeolus sphinctrinus* from México, one with spores 12-16.8 x 8.4-12 µm and another with spores 14-18.2 x 9.8-13.5 µm, and as they mentioned, it seems that there is one *Panaeolus sphinctrinus* in tropical and subtropical regions with small spores and another in temperate regions with large spores. *Panaeolus venezolanus* is close to that from the tropics and subtropics. The author even had observed some "Panaeolus sphinctrinus" with an annulus in the tropics of México, but unfortunately he did not study them.
Another species of *Panaeolus* close to *Panaeolus venezolanus* is *Panaeolus phalaenarum* (Fr.) Quél. sensu Singer (1969), reported from Chile and Europe, which also has a veil that remains as a narrow annular belt, but has spores of 13.5-17 x 5.5-11.5 x 7.7-9.4 µm. *Panaeolus semiovatus* (Sow ex Fr.) Lund. Et Nannf. (=*Anellaria*, Pearson and Dennis), a well known annulate species of the alpine or paramo vegetation, is distinguished from *Panaeolus venezolanus* by the white fruiting body as well as by the chrysocystidia and size of the spores.
This species, together with other *Panaeolus* spp. and *Psilocybe cubensis* (Earle) Sing. is used by the students in Mérida, Venezuela, as a drug that provokes gastrointestinal intoxication, as the author observed in the field and as reported by Llorca Izquierdo (1972).

Macroscopic feat.:

Cap/Pileus: 0.3-1 (1.3) cm broad. Obtusely conic, expanding to nearly plane with a distinct pronounced umbo. Margin translucent-striate most of the way to the disc when moist. Ochraceous tawny to cinnamon brown, hygrophanous, becoming pale pinkish yellow in drying.
Gills/Lamellae: Adnate to adnexed, soon seceding crowded to subdistant, narrow to moderately broad. Pale grayish yellow at first, becoming rusty cinnamon brown at maturity.
Stem/Stipe: 10-50 (70) mm long, 0.75-1 (1.5) mm thick. Equal to slightly enlarged at the base, fragile. Whitish, becoming slightly pallid yellowish brown, more grayish at the base. Surface covered with fine fibrils at first but soon smooth overall. Partial veil thin to absent.

Microscopic feat.:

Basidio/Spores: Rusty brown in deposit, (6.5) 7-9 by 4-4.5 (5) µm.
Basidia: 4-spored.
Pleurocistidia: Absent.
Cheilocystidia: 20-40 by 9-15 µm.

Habitat: Scattered to numerous in moss in and about sphagnum bogs, and in damp wet places.

Distribution: Reported from Washington, Oregon, and Michigan, probably more widely distributed. Not known from Europe.

Season: Spring, Summer and fall.

Comment: Probably active, given the bluing reaction, and containing up to 0.80% baeocystin (Repke et al. 1977). The geographical range of this species is likely to be much more extensive than the literature presently indicates. This species can be found in mossy areas of wet fields. Visually, this species is hard to distinguish from *Conocybe cyanopus*. Microscopically, these two taxa can be separated by spore size.

Dosage: Assuming the small size of this species and its macroscopic similarity to *Conocybe cyanopus*, I imagine that 40-50 small specimens, 1/3 of a fresh ounce and/or 1 dried gram would be about the same dosage as that of *Conocybe cyanopus*. This species seems to fruit to a size smaller than *Conocybe cyanopus*. (accrd. www.mushroomjohn.org)

Gills/Lamellae: (10) 13-15 mm.
Stem/Stipe: 12-23 x 0.8-2.2 mm. Cylindrical.

Microscopic feat.:

Basidio/Spores: 8.5-10 x 5.5-8 µm. Sporeprint rusty-orange brown.

Habitat: Found in a green house in Germany.

Distribution: Possibly tropical climates since it was only found once in a hothouse in Germany.

Season: Warm and after rainfalls in tropical climates?

Dosage: Unknown. And not recommended due to it's relationship with the deadly species of *Galerina*.

Comment: *Galerina steglichii* is a tiny bluing tropical(?) species that was recently discovered in a hot house in the botanic gardens of Regensburg in Bavaria (GFR). Both psilocybine and psilocine were reported by Besl as occurring in this species. Gartz also analyzed some specimens in 1994. It was baptized in honour of Wolfgang Steglich, a chemist who has done a lot of research on, among others, fungal pigments. Gartz found both psilocine and psilocybine as well as small amounts of baeocystine in this species ranging from 0.05% to 0.14% dry weight.

Partial veil cortinate, yellowish, fragile, soon disappearing and leaving a fibrillose annular zone in the superior region of the stem.

Microscopic feat.:

Basidio/Spores: Rusty brown to rusty orange to reddish cinnamon in deposit, ellipsoid in face view, inequilateral in side view, 6-9 by 3.5-4.5 µm.
Basidia: 4-spored.
Pleurocistidia: Rare, 23-35 by 5-7 µm.
Cheilocystidia: 20-38 by 5-9 µm. Flasklike to ventricose, and mostly capitate.

Habitat: Grows gregarious to cespitose on woody debris of hardwoods and conifers, wood chips, sawdust, and stumps from May to September across much of the United States (California, Oregon, Washington, Idaho, Michigan, Tennessee, Ohio, and Pennsylvania), central to northern Europe, and Japan.

Comment: Moderately active. Few people have actually experimented with this mushroom, probably because it was not widely known to be active. There may be compounds other than psilocybin, but closely related, that potentiate the experiences of the consumer. This large *Gymnopilus* has a bitter taste and is flushed with bluish tones. A slight oily farinaceous odor with hints of anise has been reported from specimens found in the Pacific Northwest.

Distribution: This species is widely distributed in the United States, Europe and in some regions of Australia.

Season: It fruits from summer through the winter depending on the location and weather.

Dosage: Large amounts of this bitter shroom are needed.

Comment: This sometimes common species name has now been changed to *Gymnopilus junonius*. This is the correct name for "Gymnopilus spectabilis," according to taxonomists and mycologists. This is a very bitter tasting mushroom and large quantities need to be consumed for the desired effects. This mushroom has been known of in Japan for many centuries as 'wa-rai-take' (laughing mushroom) and/or as 'O-wa-rai-take' (big laughing mushroom).

Gills/Lamellae: Close to crowded; broad, edges fimbriate, yellowish or pale orange, eventually orange; sometimes with reddish brown spots.
Stem/Stipe: (1) 3-7 cm long; (2) 3-8 (10) mm thick; more or less equal, or tapering in either direction; sometimes slightly, even to off-center; smooth or finely fibrous; whitish to pale orange; yellowish or rusty colored mycelium at the base of the stalk. No partial veil.

Season: Much like other Gymnopilus species it is found Late July through November, but really depends on the conditions.

Habitat: *Gymnopilus liquiritiae* is a widely distributed wood rotting mushroom, subcaespitose on conifer, seems to prefer dead hardwood in the southern regions. Much like *Gymnopilus junonius* these are found on decaying wood, both hardwoods and conifers. They are found mostly on conifers. They can grow on newly fallen trees sometimes as old as a year, but prefer older logs, fallen trees, and wood chips. Saprobic on the rotting wood of fallen hardwoods (especially in the south) and conifers (especially in the north and west); growing alone or gregariously; widely distributed; summer and fall. Singularly or in clusters, sometimes fruiting in great numbers in wood chips.

Habitat: Gregarious on rotted wood.

Distribution: The Austral Floral Zone, Chili, Argentina, Great Britain and Germany.

Season: Fall months.

Dosage: Unknown, but considering the large size of this species, caution should be taken when attempting to consume this mushrooms.

Comment: This species was first identified in Australia by mycologist John Burton Cleland as *Flammula Purpurata* (derived from the Latin *Purpuratus* - clad in purple). Cleland described this species as being found on fallen trunks of wood. *Gymnopilus purpuratus* is an agaric identified from the austral floral zone and was also collected in Chile and identified by Singer in 1951, who also identified this species from Kew gardens in Surrey. This species blues easily, taste very bitter and is probably hallucinogenic. 1992 chemical analysis of collections from Germany by Dr. Jochen Gartz of the University of Leipzig and others have demonstrated high levels of psilocine and low levels of baeocystine. Dr. Gartz reported that "since 1983, this species has been observed on heaps of pig dung and woodchips in the district Rostock, Northern G. D. R. (East Germany). It seems that this species was introduced (into Germany) with grain from Argentina used for pig forage." Gartz also noted that this species stains blue when handled and was found to be exempt of other tryptamines, muscarine, and urea.

Habitat: Solitary, gregarious to cespitose on trunks or rotting wood, in coniferous (U.S.A.) or *Pinus-Quercus* forests (Mexico).

Studied material: MEXICO: STATE OF OAXACA, Municipality of San Juan Mixtepec, 14 km W from San Juan Mixtepec, Tejocotes, Sept. 4, 1989, *Guzmán-Dávalos 4977* (IBUG). U.S.A: Idaho, Valley Co., Payette Lakes, June 28, 1958, *Smith 58394* (MICH); State of Washington, 1969, *Hatfield 3* (MICH).

Comment: This species is distinguished by the color and ornamentation of the pileus, cystidia presence and the radial pileus trama. The caulocystidia of the Mexican material are shorter and wider than those observed in the specimen Smith 58394, but both within species range. It is closely related to *Gymnopilus penetrans*, but this has a glabrous pileus, spores verruculose, pileocystidia absent and generally a yellow pigment is not dissolved when mounted in KOH. *Gymnopilus sapineus* is a widely cited species in literature, and it is known from North America, South America, Europe, Africa, Asia and Australia (Cooke, 1884-1886; Bresadola & Saccardo, 1899; Kauffman, 1918; Bresadola, 1927; Maire, 1933; Konrad & Maublanc, 1948; Kühner & Romagnesi, 1953; Hesler, 1969; Gilbertson, 1974; Guzmán, 1977-B; Pegler, 1977; Moser, 1983; Natarajan & Raman, 1983; Lindsey, 1988; Singer, 1986; Bon, 1987; Höiland, 1990); however, until now it was unknown from Mexico.

Context: Whitish to yellow-whitish. KOH staining pileus with olivaceous-green spots with purple margins; on the lamellae yellowish brown; on the stipe purple brown to almost black and on the context greenish yellow.
Odor: Farinaceous and sweet, taste bitter

Microscopic feat.:

Clamp connections present. Laticiferous hyphae present. A yellowish pigment is dissolved when mounted in KOH.

Habitat: Gregarious to cespitose in a garden on pine-wood of unknown origin.

Studied material: STATE OF JALISCO, Municipality of Zapopan, Nextipac, Guadalajara University, Institute of Botany, *Guzmán-Dávalos 4773* (Holotype, IBUG; Isotype XAL, ENCB, MICH), *3914* (IBUG), *4202* (IBUG, XAL), *4775* (OBUG), *4855* (IBUG, ENBC), *5109*, (IBUG, MICH).

Discussion: *Gymnopilus subpurpuratus* is characterized by the small fibrillose-scales on the disc, the greenish stains and the veil forming an annular zone. The green staining suggest a relationship with *Gymnopilus aeruginosus* (Peck) Sing., however, this latter species is greenish with yellow and reddish spots, more scaly, has pleurocystidia and has a different type of caulocystidia (Hesler, 1969; Imazeki & Hongo 1971 i Valensuela *et al.* 1981). It is also close to *Gymnopilus peliolepis* (Speg.) Sing., but it has reddish-purple scales, does not stain green and the cheilocystidia are fusoid or ampullaceous, non-capitate. It also is related to *Gymnopilus luteofolius* (Peck) Sing., but is distinguished by the reddish to vinaceous context, discoloring to yellowish (Singer, 1951-A & 1951-B; Hesler, 1969). *Gymnopilus luteoviridis* Thiers stains green, but has pleurocystidia and no caulocystidia (Thiers, 1959). Macroscopically, it resembles to *Gymnopilus purpuratus* (Cooke et Mass.) Sing., but that species has larger spores (Singer, 1969; Lazo, 1984). The material Guzmán-Dávalos 4202 also has spores 8-12 x 4.8-6.4 µm, that are ellipsoid-elongate in addition to the typical spores.

Comment: Weakly to mildly active, containing 0,12% psilocybin according to Hatfield et al. (1978). (Actual potency may be higher, as psilocin was not screened.) The firs reports of activity came from victims who had confused this species with *Armillaria mellea*, ht edible honey mushroom (Smith 1980). The mild taste is in contrast to the bitter flavor typical of *Gymnopilus spectabilis*, which shares an affection for hardwoods and looks similar. See also *Gymnopilus ventricosus*.

Habitat: Primarily under deciduous trees (*Fagus, Quercus, Carpinus*) and to a lesser degree under conifers (*Picea*) in woodland soils.

Comment: Weakly active, according to Stijve and Kuyper (1985). One variety, *Inocybe corydalina* var. *corydalina*, contains up to 0.32% psilocybin and 0.10% baeocystin, no psilocin. Another, *Inocybe corydalina* var. *erinaceomorpha* had 0.10% psilocybin, no psilocin and 0.034% baeocystin. (Note: the sampling was limited to only three collections.) Gurevich and Nezoiminogo (1994) reported that a collection of *Inocybe corydalina* var. *corydalina* tested negative for psilocybin but positive for muscarine, a result not confirmed by other researchers. *Inocybe corydalina* var. *corydalina* has been reported from both North America and Europe, while *Inocybe corydalina* var. *erinaceomorpha* has thus far only been reported from Europe. The former species has greenish gray fibrils near the disc, while the latter has dark brown scales but without greenish hues. See also *Inocybe coelestium*.

Inocybe haemacta

Inocybe haemacta (Berk. & Cooke) Sacc. (1887)

synonyms:
Agaricus haemactus Berk. & Cooke (1882)
Inocybe corydalina f. *haemacta* (Berk. & Cooke) R.Heim (1931)

Inocybe haemacta var. *rubra* Rea (1922)

Macroscopic feat.:

Cap/Pileus: 1.4-6.5 cm broad. Obtusely conic at first with an incurved margin, soon expanding to convex to broadly convex to plane. Margin uplifting at times with aging and sometimes without an umbo, staining a greenish gray towards the center. Covered with fibrils which appear as greenish-grey towards the center becoming pinkish where handled.
Gills/Lamellae: Narrowly adnate to almost free. Grayish brown with olivaceous tones and staining reddish near the edges and turning red-brown with spore maturity.
Stem/Stipe: 17-85 mm long by 3-10 mm thick. equal to narrow along base. solid. fine hairs. Dingy white to bright pink near the apex when young and greyish-green towards the base to nearly black with age. Odor is unpleasant. With a partial veil.

Microscopic feat.:

Basidio/Spores: 8-11.5 x 5-6.5 µm, smooth, conico-cylindrical. Sporeprint dull gray-brown in deposit.

Habitat: In clay soils in alluvian plains, or in soils enriched with debris and underneath deciduous woods with oaks (Quercus) and beeches (Fagus).

Distribution: Widespread throughout Europe but rare in the Netherlands and the British Isles.

Season: August through October.

Dosage: 1-2 grams dried.

Comment: A weak species and generally Inocybes contain muscarine yet the six species which contain psilocybine etc., apparently contain no muscarine. These Inocybes are not recommended for consumption due to the fact that most of the members of this genus are somewhat toxic to humans.

Pluteus cervinus

Pluteus cervinus (Schaeff.) P. Kumm.

---

synonyms:
Agaricus atricapillus Batsch, 1786
Agaricus cervinus Schaeff. 1774
Pluteus atricapillus (Batsch) Fayod 1889
Rhodosporus cervinus (Schaeff.) J. Schröt. 1889

Discussion: *Pluteus cervinus*, often called the "deer mushroom" in field guides, is widely distributed and common in much of North America - especially in temperate regions. It appears on deadwood, and features gills that are free from the stem. The gills are whitish at first, but soon become pink. The cap is variable in color, but is usually a shade of brown. *Pluteus cervinus* usually appears on the wood of hardwoods, but it is not very picky about what kind of wood it grows on - nor is it very picky about when it will fruit, appearing from spring to fall and even in winter in warmer climates.

Macroscopic feat.:

Cap/Pileus: 4.5-10 cm; convex at first, becoming broadly convex to nearly flat, with or without a broad central bump; tacky when fresh, but soon dry, or slightly sticky when wet; shiny; bald, or finely scaly/fibrillose over the center; often radially streaked; dark to pale brown, often with a hint of olive or gray--or occasionally nearly whitish, with a brown to brownish center; the margin usually not lined, but sometimes faintly lined in older, diminutive specimens.
Gills/Lamellae: Free from the stem; close or crowded; short-gills frequent; white at first, becoming pink and eventually becoming deep flesh color.
Stem/Stipe: 5-13 cm long; 5-15 mm thick; more or less equal, or with an enlarged base; dry; bald or, more often, finely fibrillose with brownish fibrils; whitish, discoloring brownish near the base; basal mycelium white. Flesh: Soft; white; unchanging when sliced.
Odor: Not distinctive, or somewhat radishlike; taste usually at least slightly radishlike.

Microscopic feat.:

Basidio/Spores: Sporeprint brownish pink. Spores 6-8 x 4.5-6 µ; ellipsoid; smooth; hyaline to faintly ochraceous in KOH; uni- to multiguttulate; inamyloid.
Cheilocystidia: Abundant (though often collapsing); forming a more or less continuous strip; to 50 x 15 µ; clavate to sphaeropedunculate; hyaline; thin-walled.
Pleurocistidia: 50-90 x 10-25 µ; fusiform to widely fusiform or narrowly utriform; thick-walled; hyaline; with 2-5 apical prongs or hooks; prongs usually entire rather than bifurcated, rarely branched. Intermediate cystidia variously shaped.
Epicutis: A cutis or ixocutis; elements 3-11 µ wide, hyaline to brown in KOH, smooth; terminal cells clavate to subclavate or cylindric; clamp connections absent.

Habitat: *Pluteus cervinus* is usually a woodland species, and is not generally found on woodchips in urban areas. On the deadwood of hardwoods and, less often, conifers; occasionally appearing terrestrial but actually arising from buried deadwood; growing alone, scattered, or gregariously; spring through fall.

Distribution: *Pluteus cervinus* appears to be common from the Great Plains eastward, in temperate forests (south of about the 45th parallel). Common in eastern North America from about the 45th parallel southwards; also recorded from the San Francisco Bay area.

Comment: *Pluteus cervinus* lacks clamp connections in the pileipellis; several look-alikes have clamps. *Pluteus cervinus* has pleurocystidia with entire (rather than branched or bifurcated) hooks or "antlers", its "intermediate cystidia" (immature pleurocystidia) are not consistently fusiform (like those of Pluteus petasatus and Pluteus rangifer), and its cheilocystidia are frequent and form a consistent strip along the edge of the gill. The spores of *Pluteus cervinus* are usually about 5-6 µ wide (Pluteus petasatus has slightly more narrow spores).

Pluteus cyanopus

Pluteus cyanopus Quel.

Macroscopic feat.:

Cap/Pileus: 3-7 cm broad, convex to broadly convex, expanding with age to broadly convex to plane. Gray to gray greenish, to blueish gray, darker towards the disc. Surface smooth to finely scaly near the center.
Gills/Lamellae: Free, not attached. Pallid to cream, soon pinkish to salmon coloured at spore maturity.
Stem/Stipe: 40-100 mm long by 2-6 mm thick. White to grayish green, often with bluish tones. Flesh often bruising bluish where injured, especially near the base. Base of stem bruising bluish. more or less equal or slightly swollen at the base, flesh white with grayish-green to bluish-green tones, especially near the base. Ring absent. Firm, full or stuffed.

Microscopic feat.:

Basidio/Spores: Pinkish in deposit, smooth, ellipsoid to egg shaped, 7-8.5 by 5-6 µ.
Pleurocistidia: Fusiform to lageniform, with or without hooked ends, 58-90 by 10-22 µ and with an apex 5-10 µ thick.
Cheilocystidia: Pear shaped to clavate to cylindrical or slightly lageniform, 30-85 by 8-20 µ.

Season: August through November.

Distribution: Growing in the woods mostly on hardwoods in the forests of the pacific northwest however, reports have been found of this species growing on conifers in an old growth area.

Habitat: Mostly singularly, but sometimes in small groups or two or three in a cluster.

Blueing: The base will show obvious blue bruising, the cap may also have blue spots where handled.

Dosage:

- Lvl. 1 - 2.2g
- Lvl. 2 - 3.8g
- Lvl. 3 - 6.7g
- Lvl. 4 - 10.3g
- Lvl. 5 - 14.0g

Notes: *Pluteus salicinus* for any other Pluteus sp. because they will be blue on the base or will blue almost immediately after picked. Weakly to moderately active. Stijve and Kuyper (1985) reported 0.05-0.25 psilocybin, no psilocin, and from zero to 0.008 baeocystin. Christiansen et al. (1984) found 0.35 psilocybin and 0.011 psilocin. See also Saupe (1981) and Stijve and Bonnard (1986). The Field Guide to Mushrooms of Southern Africa by G.C.A. Van der Westhuizen and Albert Eicker (1994) lists *Pluteus salicinus* as edible although their description lacks any mention of a bluing reaction. This species may have races that vary in their chemical content from region to region. Heres the differences between *Pluteus salicinus* and *Pluteus cyanopus*. *Pluteus cyanopus* - Cap wrinkled in the center; cap margin lined; gills well spaced, their edges not discoloring; odor and taste mild; spores 6-7 x 5-6 µ; cystidia without spines.
Pluteus salicinus - Cap center not wrinkled; cap margin not lined; gills crowded, their edges discoloring grayish; odor and taste unpleasant; spores 7-9 x 5-6 µ; cystidia with spines.
